On the Distribution of Prime Squares and Its Applications

Full Unedited Blueprint

Historical development archive

Prepared for Hamed Mousavi
28 October 2026

This volume brings together every one of the 1,303 original files preserved in the saved blueprint archive. The Markdown notes contain 493,795 whitespace-separated words. Their contents have not been mathematically rewritten or condensed.

The archive includes 54 topic and historical planning notes, 1,224 individual checkpoint notes (42 through 1265), seven batch summaries, an earlier README, four LaTeX source files, three CSV inventories, nine JSON records, and the original initial-blueprint PDF.

Historical status. Earlier notes contain intermediate errors, superseded replacements, earlier titles, and progress statements that were true only at the recorded checkpoint. They are preserved here as development history. The current compact blueprint and current assumption catalogue remain the guides to the final conditional scope.

Formatting and preservation. Markdown and mathematics are typeset, long source lines are wrapped, and the files are placed in a new reading order. Original source files and their checksum manifest are supplied in the companion source bundle; a byte-identical copy of that bundle is embedded in this PDF. The original initial-blueprint PDF is appended at the end.

Verification scope. This compilation changes no Lean proofs and performs no new Lean build or mathematical audit. The verification claims inside individual notes are reproduced historical reports, not new claims made by this compilation.

Contents and reading order

Use the PDF outline to jump to any individual source file. Checkpoint notes are in numerical order. Relative links in the archived Markdown are printed as text; their original destinations remain in the attached source files.

Annular_Boundary_and_Remainder_Bounds.md

Bounding the actual integration-by-parts terms

For $W_\beta(t) = t^{\beta-2}$ and $E_\theta(t) = e^{-2\pi i\theta t^2}$, the previous identity reduces decay to the boundary $[W_\beta(t)E_\theta(t)]_{N/2}^{N}$ and remainder $\int_{N/2}^{N} W'_\beta(t)E_\theta(t)\,dt$.

For $N \geq 2,\ 0 \leq \beta \leq 1$, every t in the annulus is at least one. Monotonicity in the exponent and in the positive base gives

$$|W_\beta(t)| \leq 2/N, \qquad |W'_\beta(t)| \leq 8/N^2.$$

The first estimate only requires beta<=1. The second also uses beta>=0 to bound $|\beta - 2|$ by two. The oscillation has norm one.

The triangle inequality bounds the two boundary terms together by $4/N$. The annulus has length $N/2$, so bounding the remainder integrand by $8/N^2$ also gives $4/N$. These estimates concern the actual integrals, with no hypothesis asserting their decay.

Module	New named theorems
AnnularBoundaryBounds.lean	7

Scope

The proof is unconditional. The next unit will combine these bounds with exact integration by parts and the normalization 1/N. This is a supporting step toward the source model estimates; it does not complete the full minor-arc lemma or the high-low decomposition.

<!-- checkpoint-verification -->

Verification

All 99 project modules and the root were freshly rebuilt: 3614 jobs pass without warnings/errors. All 789 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 101 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

Annular_Gauss_Model_Tails.md

Uniform tails for the actual Gauss models

The model is

$$G_{N,q,\chi,\kappa,\beta,a}(\theta) = \mathfrak{s}(a,q)M_N^1(\theta) - \mathfrak{s}_\chi(a,q)\kappa M_N^\beta(\theta).$$

It uses the project's genuine totient-normalized sums and the genuine annular integrals, with the source sign and phase.

The already proved unconditional bound for all complex Dirichlet characters, applied at epsilon=1/12, gives one constant C such that both Gauss coefficients are at most $Cq^{-5/12}$ for unit a. The principal coefficient is the character-one specialization of the same proved theorem.

For $N \geq 2,\ 0 \leq \beta \leq 1,\ |\kappa| \leq 1$, the half bound for each integral gives

$$|G(\theta)| \leq Cq^{-5/12}.$$

If $q \leq R$ and $|\theta| \geq R/(qN^2)$, each integral is at most $2q/(\pi R)$, so

$$|G(\theta)| \leq (4C/\pi)R^{-5/12}.$$

The required power comparison $q^{-5/12}q/R \le R^{-5/12}$ is proved with positive bases. Multiplication by the actual cutoff $\eta_s \in [0,1]$ does not increase the norm.

Module	New named theorems
AnnularGaussModelBounds.lean	5

Scope

All inputs used here are proved in the pinned project or Mathlib. No new external analytic estimate is assumed. The coefficient kappa remains a parameter with norm at most one; the exceptional-conductor indicator will be an allowed specialization. This is a model-tail result, not a minor-arc bound for the actual prime sum, and it does not complete the global approximation.

<!-- checkpoint-verification -->

Verification

All 103 project modules and the root were freshly rebuilt: 3622 jobs pass without warnings/errors. All 818 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 105 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Annular_Model_Frequency_Decay.md`

Frequency decay for the genuine annular models

The exact integration-by-parts identity and the two bounds $4/N$ give, for $N \ge 2,\ 0 \le \beta \le 1$,

$$4\pi|\theta|\,|M_N^\beta(\theta)| \le 8/N^2.$$

Thus, at nonzero frequency,

$$|M_N^\beta(\theta)| \le \frac{2}{\pi|\theta|N^2}.$$

Both statements are proved for the actual real integral. Its interval avoids the stationary point zero; no external oscillatory-integral theorem is assumed.

Combining the decay with the already proved half bound yields a global profile, valid also at zero:

$$|M_N^\beta(\theta)| \le \frac{1/2 + 2/\pi}{1 + N^2|\theta|}.$$

Finally, for positive real q and R, outside the rational arc

$$|\theta| \ge R/(qN^2) \quad \Longrightarrow \quad |M_N^\beta(\theta)| \le 2q/(\pi R).$$

This last estimate is intended for the model-tail argument with q<=R. It retains prime-square spatial scale N^2.

Module	New named theorems
AnnularModelDecay.lean	5

Scope

No deep analytic input is used. These uniform-beta estimates supply the decay needed for model tails. They do not claim the extra N^(beta-1) factor in the manuscript's displayed estimate. The independent minor-arc gap is unchanged, and the full approximation and decomposition remain open.

<!-- checkpoint-verification -->

Verification

All 100 project modules and the root were freshly rebuilt: 3615 jobs pass without warnings/errors. All 794 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 102 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Annular_Model_Integration_by_Parts.md`

Exact integration by parts on the quadratic annulus

Write $E_\theta(t) = e^{-2\pi i\theta t^2}$, $W_\beta(t) = t^{\beta-2}$, and $K_\theta = -4\pi i\theta$. For $N \geq 1$, all powers in this proof are evaluated on $[N/2, N] \subset (0, \infty)$.

The new module proves the derivatives and integrability needed for the exact complex identity

$$K_\theta \int_{N/2}^{N} t^{\beta-1} E_\theta(t)\, dt = [t^{\beta-2} E_\theta(t)]_{N/2}^{N} - \int_{N/2}^{N} (\beta-2) t^{\beta-3} E_\theta(t)\, dt.$$

It holds for every real beta and theta. The normalization $1/N$ is not yet applied in this identity. Multiplying by K_θ instead of dividing by it keeps zero frequency within the statement.

The power identity $t^{\beta-2}t = t^{\beta-1}$ is justified for positive real t. No periodicity is assumed for a noninteger integration variable, and the genuine phase derivative from QuadraticOscillation.lean is used.

Module	New named theorems
AnnularModelIntegrationByParts.lean	6

Scope

These are unconditional calculus proofs. Bounds for the two boundary terms and the remainder integral are the next step. The full minor-arc deduction and the analytic decomposition remain open. This unit requests no manuscript change.

<!-- checkpoint-verification -->

Verification

All 98 project modules and the root were freshly rebuilt: 3613 jobs pass without warnings/errors. All 782 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 100 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Annular_Model_Size_and_Mass.md`

Uniform bounds and mass for the actual annular models

This unit concerns the integral already used in the genuine major-arc formula:

$$M_N^\beta(\theta) = \frac{1}{N} \int_{N/2}^{N} t^{\beta-1} e^{-2\pi i\theta t^2}\, dt.$$

The endpoints are real, including when N is odd. The integral is not replaced by a discrete sum or by an abstract bounded function.

For $N \geq 1$ and $\beta \leq 1$, the power density decreases on this positive annulus. Since the oscillation has norm one,

$$|M_N^\beta(\theta)| \leq \tfrac{1}{2}(N/2)^{\beta-1}.$$

Consequently $N \geq 2,\ \beta \leq 1$ gives the uniform bound $1/2$, including the ordinary case $\beta = 1$. Positivity of beta is not needed for these size bounds because the interval is bounded away from zero.

For $\beta > 0$, the derivative of t^β/β gives the exact identity

$$M_N^\beta(0) = \frac{N^\beta - (N/2)^\beta}{N\beta}.$$

The Lean proof uses the previously proved derivative, proves interval integrability on the positive annulus, and applies the complex-valued fundamental theorem of calculus.

Module	New named theorems
AnnularModelSize.lean	5

Scope

No external analytic input is used. This proves the uniform-size part needed in the approximation argument; frequency decay is the next task. The full source minor-arc deduction remains unresolved as documented in Ren_Input_and_Annular_Bound.md. No manuscript modification is requested by this unit.

<!-- checkpoint-verification -->

Verification

All 97 project modules and the root were freshly rebuilt: 3612 jobs pass without warnings/errors. All 776 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 99 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Cohen_Identity.md`

Quadratic Cohen identity: completed formalization

Source: `sources/current/Draft5.tex`, Lemma 3.1, label `l:cohenquadratic`, on page 17 of the supplied 99-page PDF. The complete identity and its uniform bound are proved in Lean. This is the first complete numbered paper lemma in the project; the other paper results remain open.

Statement and definitions

For a positive integer q, write A_q for the units of Z/qZ and define

$$c_q(m) = \sum_{a \in A_q} \exp(2\pi i a m/q), \qquad C_q(n) = \sum_{r \in A_q} c_q(n - r^2).$$

Let $a = v_2(q)$ and $d = q/2^a$. The checked global statement is

$$C_q(n) = |\mu(d)| T_a(n) \prod_{\substack{p \mid q \\ p > 2}} \begin{cases} p+1, & \left(\frac{n}{p}\right) = 1, \\ 1-p, & \left(\frac{n}{p}\right) \neq 1. \end{cases}$$

It holds for every positive q and every integer n, including negative n. The modulus-one product is empty and has value 1. The Legendre symbol has value zero when p divides n, and that case is included in the second branch.

The 2-adic factor is represented explicitly in the code:

Exponent a	Nonzero values of T_a(n)	All other residues
0	1 for every n	—
1	+1 at n=1 modulo 2; -1 at n=0 modulo 2	—
2	+4 at n=1 modulo 4; -4 at n=3 modulo 4	0
3	+16 at n=1 modulo 8; -16 at n=5 modulo 8	0
a>=4	None	0

This is the paper's T_a, with the signs spelled out. The equivalence is also checked: `twoAdicCohenFactor_one` proves $T_1(n) = (-1)^{n+1}$, using integer powers, and `twoAdicCohenFactor_small` proves $T_a(n) = \phi(2^a)c_{2^a}(n-1)$ for a=2,3. The explicit residue cases give the zero and signed-square assertions in the paper.

The formalization also proves

$$|C_q(n)| \le 16\,|\mu(q/2^a)| \prod_{p|q}(p+1).$$

The absolute constant 16 suffices for the paper's implied-constant bound. The sharper constant 16/3 is not asserted as a universal Lean theorem here.

1. Genuine exponential sums

`PrimeSquares/QuadraticCohen.lean` uses Mathlib's `ZMod.stdAddChar`, whose value on an integer residue is the displayed complex exponential. It defines c_q and C_q by finite sums over a complete residue system filtered by `IsUnit`. `sum_unit_filter_eq_sum_units` proves the equivalence with summing directly over the unit group. Modulus zero is excluded from these definitions by `NeZero q`.

The assembly file introduces `cohenCorrelation q n` as an integer-input interface. `cohenCorrelation_eq` proves that it is exactly C_q(n) whenever q>0. Its arbitrary zero extension at q=0 is used only to apply the standard multiplicative-function factorization theorem; q=0 is excluded from the main identity and bound.

2. Odd prime factor

Additive-character orthogonality gives

$$\sum_{a \bmod p} e(am/p) = \begin{cases} p, & m = 0 \pmod p, \\ 0, & m \neq 0 \pmod p. \end{cases}$$

For prime p, units are precisely nonzero residues, so subtracting the zero term proves $c_p(m) = p-1$ when m=0 and -1 otherwise.

Let R be the number of all roots of $r^2 = n$ modulo p. Summing over all r and subtracting the r=0 summand gives

$$C_p(n) = pR - p - c_p(n).$$

Mathlib's `legendreSym.card_sqrts` proves $R = (n/p) + 1$ for odd p. If p divides n, R=1 and the formula gives 1-p. Otherwise the Legendre symbol is +1 or -1, giving p+1 or 1-p. This proves `quadraticRamanujanSum_odd_prime` with no assumption that n is a unit.

3. Higher prime powers by a unit permutation

The code uses one algebraic argument for both higher-power vanishings, in place of the paper's separate Hensel-lifting count and 2-adic permutation.

Let R be a commutative ring, $t^2 = 0$, and r a unit. Then

$$F_t(r) = r + t/r$$

is a unit: its multiplicative inverse is $r^{-1} - tr^{-3}$. Moreover F_{-t} is the inverse permutation to F_t, and

$$F_t(r)^2 = r^2 + 2t.$$

All three assertions are proved in `UnitSquareShift.lean`, including bijectivity and the explicit inverse. Define the unit quadratic Gauss sum

$$S_q(b) = \sum_{r \in A_q} e(br^2/q).$$

For unit b, reindexing by F_t gives

$$S_q(b) = e(2bt/q) S_q(b).$$

When $2t \neq 0$ modulo q, primitivity of the standard character and invertibility of b make the multiplier different from 1. Thus S_q(b)=0. Expanding c_q and interchanging the finite sums then gives

$$C_q(n) = \sum_{b \in A_q} e(bn/q) S_q(-b) = 0.$$

For $q = p^k$, p odd and k>=2, take $t = p^{k-1}$. The divisibility $q \mid t^2$ follows from 2k-2>=k, while 2t is nonzero since p does not divide 2. For $q = 2^a$, a>=4, take $t = 2^{a-2}$. Again t squared is zero modulo q, and $2t = 2^{a-1} \neq 0$. The inequalities, divisibility, and nonvanishing are proved for all exponents, not checked up to a bound.

4. Small powers of two

For q=2,4,8 every unit square is 1. Kernel-reduced `decide` checks these finite unit assertions and their counts, giving

$$C_2(n) = c_2(n-1), \quad C_4(n) = 2c_4(n-1), \quad C_8(n) = 4c_8(n-1).$$

To evaluate c_4 and c_8, subtract the even residues from the complete additive-character sum. `stdAddChar_scale` identifies the even-residue sum with the complete character sum at half the modulus. Orthogonality gives

$$c_4(m) = \begin{cases} 2, & m = 0 \pmod 4, \\ -2, & m = 2 \pmod 4, \\ 0, & \text{otherwise}, \end{cases}$$

and c_8 has values +4 at 0, -4 at 4 modulo 8, and zero elsewhere. These are symbolic proofs of the complex-valued sums. Finite unit sets and projection kernels are the only computational residue checks. The modulus-one case uses the trivial ring's unit and character conventions and gives C_1=1.

5. CRT multiplicativity with the normalization proved

For coprime positive u,v, CRT identifies the units modulo uv with the product of the two unit groups. For the coefficients inside c_q use

$$(b, c) \longmapsto vb + uc \pmod{uv}.$$

Its CRT coordinates are (vb,uc). Multiplication by v modulo u and by u modulo v are unit permutations, so this is a bijection of the coefficient sets. The character-scaling identities

$$e(vj/(uv)) = e(j/u), \qquad e(uj/(uv)) = e(j/v)$$

are proved from the actual exponential formula. Reindexing the coefficient sum therefore proves c_(uv)(m)=c_u(m)c_v(m). Reindexing the square-shift variable by ordinary CRT then proves

$$C_{uv}(n) = C_u(n) C_v(n).$$

This avoids assuming an incorrect unscaled factorization of the standard character itself. Both multiplicativity theorems include u=1 or v=1.

6. Prime-factor and Mobius assembly

`cohenCorrelation_factorization` applies multiplicativity to the canonical prime-power factorization. At an odd prime, the local contribution is its Legendre factor if the exponent is one, and zero for every higher exponent. Consequently the product of exponent-one indicators is 1 exactly when the odd modulus is squarefree. `primeFactor_indicator_eq_abs_moebius` identifies this product with $|\mu(d)|$.

Mathlib's prime-power projection gives

$$q = 2^a d, \qquad d > 0, \qquad 2 \nmid d,$$

and the prime factors of d are exactly the prime factors of q greater than 2. Combining the odd product with the complete T_a factor proves the global identity. This includes q=1 and all nonsquarefree odd parts.

7. Uniform bound

The explicit local cases prove $|T_a(n)| \leq 16$ for every a,n. Each odd Legendre factor has absolute value at most p+1. The Mobius absolute value is nonnegative, so taking norms of the product gives the displayed bound with constant 16, after enlarging the odd-prime product to all prime factors. This is `quadratic_cohen_bound`.

Verification and scope

The root project imports all nine modules. The complete build and transitive axiom audit cover all 57 named project theorem declarations, including the initial support lemmas. Only `propext`, `Classical.choice`, and `Quot.sound` occur. No deep analytic input, extra mathematical axiom, proof placeholder, or `native_decide` is used in this development.

The exact Python experiment over every n modulo every 1<=q<=512 passed 131,328 cases. It uses the classical Ramanujan divisor formula and is separate from the universal Lean proof. Its sharper finite bound check with constant 16/3 is not needed for the formal bound with constant 16.

Lemma 3.1 is complete. The next finite-arithmetic targets are the ordinary Cohen identity, `l:progressioncohen`, and `l:sumoverramanujan`. The rest of the paper, including its headline theorems, remains open.

`Conductor_Refinement.md`

Lemma 3.27: the complete conductor-sensitive refinement

Checkpoint 12, 22 October 2026. The full statement is proved in Lean by an alternative elementary argument, including all three estimates, the logarithmic consequence and the support condition. No extra mathematical hypothesis is used. The proof actually permits any real character at the original level; primitivity is unnecessary for this choice of majorant.

The main declaration is `PrimeSquares.conductor_sensitive_refinement` in `PrimeSquares/ConductorRefinement.lean`. This checkpoint is a proof of this lemma, not of the paper's headline theorems.

Source identification and exact scope

The archived `sources/current/Draft5.tex` and its reference map identify:

Source item	Stable label	Typeset number	PDF page
Previous uniform twisted Gauss bound	`l:Gcharbound`	3.24	22
Current lemma	`l:exceptionalarithmetic`	3.27	23
Three estimates	`e:exceptionalarithmetic`	3.28	23
Support condition	`e:sqfreeconds`	3.29	23

Earlier checkpoint 11 prose incorrectly used 3.22 for `l:Gcharbound` and 3.23 for `l:exceptionalarithmetic`. The current reports, inventory and provenance use the reference-map numbers. The Lean statements were already tied to the correct stable source labels. No manuscript correction is needed.

Fix a positive integer q_0 and a real Dirichlet character χ_0 modulo q_0. For each positive integer d, let χ be its actual induced character modulo $q_0 d$, using Mathlib's `DirichletCharacter.changeLevel`. Write

$$s_\chi(a,q)=\frac{1}{\phi(q)}\sum_{r\in(\mathbb{Z}/q\mathbb{Z})^\times}\chi(r)e(-ar^2/q),\qquad F_\chi(x,q)=\sum_{a\in(\mathbb{Z}/q\mathbb{Z})^\times}s_\chi(a,q)e(ax/q).$$

These are the actual definitions `twistedSquareSum` and `twistedSquareCorrelation`, with the paper's minus sign and totient. All residue classes x are included; the second estimate requires a unit coefficient a, exactly as in the paper. Integer inputs are their residue classes. Modulus one and imprimitive characters are included.

`conductorSigma` is the maximum of the norms over $j=0,\dots,5$ and the units modulo $q_0 2^j$. Since multiplication is commutative, these are exactly the paper's moduli $2^j q_0$. `dyadicTwistNorm` forms the inner finite maximum; `conductorSigma` forms the outer one. Finite suprema are taken in the nonnegative reals and then coerced to the reals. The checked lower-bound and upper-bound lemmas ensure this is the actual maximum, rather than an assumed upper bound. `conductorRho` and `conductorCorrelationProduct` are exactly

$$\rho(d)=\prod_{p\mid d}(1-p^{-1/2})^{-1},\qquad G(d)=\prod_{p\mid d}\frac{p+1}{p-1}.$$

The explicit admissible choice in this proof is

$$\mathcal{B}_0=64\,8^{\omega(q_0)}\sqrt{q_0}.$$

The combined Lean theorem proves, with an absolute positive constant C, uniform in q_0, χ_0, d, x and a,

$$\mathcal{B}_0\ge 1,\qquad |F_{\chi_{q_0 d}}(x,q_0 d)|\le \mathcal{B}_0 G(d),$$
$$|s_{\chi_{q_0 d}}(a,q_0 d)|\le 32\sigma_0 d^{-1/2}\rho(d),\qquad \sigma_0\sqrt{\mathcal{B}_0}\le C q_0^{-1/25},$$
$$(1+\log q_0)\sigma_0\sqrt{\mathcal{B}_0}\le C.$$

If the sum is nonzero for any unit coefficient, it also proves

$$d=2^\nu d_1,\quad \nu\le 5,\quad d_1>0,\quad d_1 \text{ squarefree},\quad (d_1,2q_0)=1.$$

The natural-number convention makes $\nu\ge 0$ automatic. For positive d_1, squarefreeness is the paper's condition $\mu^2(d_1)=1$.

The paper's proof proposes the sharper choice $\mathcal{B}_0\asymp\prod_{p\mid q_0,\,p>2}2p/(p-1)$. That additional comparison is not part of the lemma's statement and is not claimed here. The larger explicit choice above satisfies every stated conclusion and avoids real primitive conductor classification. The archived manuscript has not been edited.

1. Real characters and multiplication by squares

For a character on a finite unit group, complex conjugation equals inversion. Consequently χ has real values if and only if $\chi^2=1$, equivalently χ takes only the values 0, 1 and -1. Lean proves this equivalence in `dirichletCharacter_quadratic_iff_real`. It also proves that `changeLevel` preserves the quadratic predicate.

At every unit v, a quadratic character satisfies $\chi(v^2)=1$. Thus multiplication of a unit r by a unit square leaves $\chi(r)$ unchanged. This fact supplies the character invariance needed for the cancellation argument; it is not an unstated assumption about induced characters.

2. A square-preserving shift forces exact cancellation

Let t,s be residues modulo q with

$$t^2 = s^2 = 0, \qquad 2s = t, \qquad 2t \neq 0.$$

The existing `squareShiftEquiv` is the unit permutation r↦r+t/r. Its inverse and the identity

$$(r + t/r)^2 = r^2 + 2t$$

were already checked in `UnitSquareShift.lean`. The new proof shows that

$$r + t/r = r(1 + s/r^2)^2.$$

Here $1+s/r^2$ is a unit, with inverse $1-s/r^2$. Thus the permutation also preserves χ(r) for every quadratic χ. Reindexing the genuine twisted Gauss sum U gives

$$U_\chi(a, q) = e(2at/q)U_\chi(a, q).$$

For a unit a, the additive character is injective and 2at≠0. The phase is therefore different from one, forcing Uχ(a,q)=0. This is an exact identity, with no asymptotic input. The normalized sum vanishes as well.

There is also a separate checked parity cancellation: if χ(-1)≠1, then reindexing by r↦-r gives a zero twisted sum for every coefficient, including nonunits. The main support proof does not need to classify which local characters are odd.

3. Vanishing at the full modulus

The shift can be applied directly at any modulus q, without first decomposing χ into local characters.

If an odd prime square p^2 divides q, write $q=p^2m$ and take

$$t = pm, \qquad s = \frac{p+1}{2}t \pmod q.$$

Then pt=0 modulo q, $t^2=s^2=0$, and 2s=t. Moreover $0<2pm<p^2m$, so 2t≠0.

If 64 divides q, write q=64m and take t=16m, s=8m. Again $t^2=s^2=0$, 2s=t, and 2t=32m is nonzero modulo q. Lean checks all divisibility, positivity, unit and phase conditions, including even moduli in the odd-prime argument.

It follows that a nonzero unit-coefficient sum has

$$v_2(q) \leq 5, \qquad v_p(q) = 1 \text{ for every odd } p \mid q.$$

For $q=q_0d$, remove the power of two from d to obtain d_1. Its odd prime exponents are at most one. An odd prime dividing both d_1 and q_0 would have its square dividing q, a contradiction. This proves the entire support condition. It holds even for a quadratic character at level q_0d that was not specified as induced.

4. Exact CRT for the induced sums

Let (m,n)=1 and let χ modulo mn be induced from a character χm modulo m. The unit CRT equivalence sends r to (rm,rn), and the induced character has value χm(rm). This follows from the actual definition of `changeLevel`.

For a residue a modulo mn, put

$$a_m = (a \bmod m)n^{-1} \pmod m, \qquad a_n = (a \bmod n)m^{-1} \pmod n.$$

Both are units when a is a unit. The standard additive character satisfies the checked CRT identity with these inverse-modulus factors. Finite reindexing and φ(mn)=φ(m)φ(n) then give

$$s_\chi(a, mn) = s_{\chi_m}(a_m, m)s_1(a_n, n).$$

The inverse coefficients are retained explicitly in `induced_twistedSquareSum_coprime_mul`; unscaled multiplicativity at a fixed coefficient is not assumed.

Opening the weighted Fourier sum in the other order gives

$$F_\chi(x,q)=\frac{1}{\phi(q)}\sum_{r\in(\mathbb{Z}/q\mathbb{Z})^\times}\chi(r)c_q(x-r^2).$$

Ramanujan-sum CRT and character induction now give

$$F_\chi(x,mn)=F_{\chi_m}(x \bmod m,m)F_1(x \bmod n,n).$$

There are no inverse factors in x in this latter identity. The Fourier identity and correlation factorization are proved separately from the quadratic Gauss factorization.

5. The correlation estimate

The earlier unconditional Lemma 3.24 gives the finite bound

$$|s_\chi(a,m)|\le 8^{\omega(m)}/\sqrt{m}.$$

Summing norms over the φ(m) unit coefficients and using φ(m)≤m yields

$$|F_\chi(x,m)|\le 8^{\omega(m)}\sqrt{m}.$$

If m=q₀2^ν with ν≤5, then ω(m)≤ω(q₀)+1 and √m≤8√q₀. Hence this is at most the chosen $\mathcal{B}_0$.

If all unit-coefficient sums at q vanish, the correlation is zero. Otherwise the support theorem supplies d=2^νd₁. Set m=q₀2^ν, n=d₁; they are coprime. For the principal correlation at the odd squarefree n, the earlier exact Cohen factors and φ(n)=∏p|n(p-1) give

$$|F_1(x,n)|\le G(n).$$

Every factor in G is at least one. Since n divides d, G(n)≤G(d). The checked CRT identity proves the first estimate with constant one.

6. The individual-sum estimate

Use the same support decomposition. The norm of the m-part of the CRT product is bounded by σ₀ by its exact definition. The previous unconditional principal product bound, with constant four, gives

$$|s_1(a_n,n)|\le\frac{4}{\sqrt{n}}\prod_{\substack{p\mid n\\ p>2}}(1-p^{-1/2})^{-1}.$$

Each factor of ρ is positive and at least one, so this product is at most ρ(n)≤ρ(d). Also √d≤8√n. Consequently

$$|s_\chi(a,q)|\le\sigma_0\frac{4}{\sqrt{n}}\rho(n)\le 32\sigma_0 d^{-1/2}\rho(d).$$

Zero sums are handled explicitly. The proof never divides by σ₀ and thus includes the σ₀=0 case.

7. Decay and the logarithmic consequence

Apply the earlier uniform bound with ε=1/8. Since q₀2^j≥q₀ and the exponent -3/8 is negative, the finite maximum defining σ₀ satisfies

$$\sigma_0\le Sq_0^{-3/8}$$

with an absolute S>0, for every complex χ₀. Put D=8^ω(q₀)≥1. The majorant satisfies

$$\sqrt{\mathcal{B}_0}=8\sqrt{D}\,q_0^{1/4}\le 8Dq_0^{1/4}.$$

The already proved elementary prime-factor absorption, used with ε=1/16, gives D≤Aq₀^(1/16), with an absolute A>0. Multiplication gives

$$\sigma_0\sqrt{\mathcal{B}_0} \le 8SAq_0^{-1/16} \le 8SAq_0^{-1/25}.$$

The comparison uses $q_0 \ge 1$. No restriction $p \equiv 1 \pmod 4$, prime-distribution estimate, Weil bound or real-character classification is required for this alternative choice of majorant.

Finally, the checked elementary logarithm bound gives

$$\log q_0 \le 25q_0^{1/25}, \qquad 1 + \log q_0 \le 26q_0^{1/25}.$$

Multiplying the decay estimate proves the logarithmic conclusion. The combined theorem takes one positive constant large enough for both conclusions, before quantifying q_0 and χ_0. Uniformity is therefore part of the formal statement.

Files and proof boundary

Module	Checked role
`QuadraticTwistCancellation.lean`	Real/quadratic equivalence, induction, square shift, parity and full-modulus vanishing
`TwistedSupport.lean`	Prime exponents and the exact relative support decomposition
`InducedTwistCRT.lean`	Actual `changeLevel`, numerator CRT and normalized CRT
`TwistedCorrelation.lean`	Actual Fourier sum, Ramanujan identity, induced CRT and finite bound
`ConductorFactors.lean`	Exact σ_0 maximum, ρ, G, B_0, positivity and divisor monotonicity
`ConductorEstimates.lean`	The first two estimates with constants 1 and 32
`ConductorDecay.lean`	Uniform $q_0^{-1/25}$ decay and logarithmic conclusion
`ConductorRefinement.lean`	Full combined source statement, strengthened to all real characters

All are under `PrimeSquares/`. No proof placeholders or new mathematical axioms are used. The ordinary Lean foundations `propext`, `Classical.choice` and `Quot.sound` remain the audit whitelist. Neither Siegel--Walfisz nor PNT is an input to this lemma. The separate Lemma 3.21 still has its two explicit PNT-limit hypotheses; their external bridge remains unintegrated.

Verification and independent experiments

The fresh project build checks all 40 project modules. The transitive axiom audit covers all 321 named project theorems, including the 49 added here. The source scan covers 42 Lean files. These are infrastructure counts, not counts of numbered paper results. Full logs are in `verification/`.

`scripts/check_conductor_refinement.py` uses exact signed integer polynomials, cyclotomic reduction, integer Ramanujan sums and rational comparisons. The recorded experiment has zero failures:

Check	Range	Cases
All real characters and all unit coefficients	$q=1,\dots,128$	452 characters; 16,754 coefficients
Higher-power vanishing	Same range	2,968
Odd-character vanishing, including nonunit coefficients	Same range	13,937
Explicit shift, square ratio, character invariance and unit permutation	Same range	2,968 unit cases
Relative conductor support	Same range	723
Fourier identity with source sign	$q \le 32$	1,561
Induced Gauss CRT with inverse coefficients	$mn \le 96$	20,331
Induced correlation CRT	$mn \le 96$	41,144
First estimate with the explicit B_0, checked by squaring	$q \le 128$	111,520

The induced-level checks include 1,048 pairs of a real base character and a strictly larger level. The σ_0 estimate and its unbounded uniform decay are established by Lean, not by a finite numerical claim. These experiments are independent finite error checks and do not replace the formal proof.

The next dependency stage is the abstract high--low argument in Theorem 4.1 (`t:improvinggeneral`), followed by its application to the prime-square operators. That work is not part of this checkpoint.

`Current_Roadmap.md`

Dependency-driven roadmap for Draft5

Source: the archived 99-page paper in `sources/current/`, with the accepted Lemma 3.14 fragment in `sources/updates/` and status in `docs/SOURCE_UPDATE_08.md`. Progress is organized by mathematical dependencies; the statement inventory preserves the section and label correspondence. This avoids redoing definitions when a proof in a later section supplies an input used earlier.

Stage	Main work	Paper location	Checkpoint status
0	Lock sources, reproduce references, state the trust boundary	Whole paper	Current files locked; 58 statements inventoried
1A	Quadratic Cohen identity: prime and prime-power local factors	Section 3, `l:cohenquadratic`	Complete Lemma 3.1; see Cohen_Identity.md
1B	CRT and the global product; progression-restricted correlations	Remaining first part of Section 3	Complete 3.11, 3.12, accepted 3.14/3.16 and original 3.20
1C	Gauss-sum bounds and exceptional-character arithmetic	Remaining Section 3	Full 3.21 with explicit PNT limits; full 3.24 for all complex characters and full 3.27 for all real characters, both unconditional
2	Abstract high--low optimization and improving inequalities	Section 4, Theorem 4.1 and Corollary 4.15	Complete: both abstract endpoints, full strong interior interpolation and p=2, actual complex lp operators, exact N scaling and uniform constants
3	Establish the prime-square high--low inputs and connect the first main theorem	Section 6, Proposition 4.19 and Theorem 1.1	The actual current user upload is matched to the completed formalization in the agreed conditional scope. No internal numbered source claim remains open.
4	Stopping intervals, local estimates, sparse recursion	Section 5, `t:sparsebound`	Both source Theorem1.3 clauses complete conditional at checkpoint828; actual sparse major subsets and all-cutoff maximum are proved. General auxiliary source lemmas remain partial.
5	Quantitative maximal and Orlicz estimates	Section 7, `t:orlicz-maximal`	Partial at checkpoint846: gauge, scalar growth/moment, finite layers and general modular deductions proved; actual IW low/high, restricted bound, strong lp and ergodic conclusions unfinished.
6	Local density correlations and the badness criterion	Section 8, first part of `t:pet`	Open
7	Sieve reductions, local densities, circle method, final error assembly	Sections 9--11, `t:repmotthm`	Open; earlier finite support lemmas available

Within each stage:

1. Expand the selected statement into definitions and a dependency graph, with all parameter restrictions and exceptional cases visible.
2. Find the relevant Mathlib declarations in the pinned source before writing replacement infrastructure.
3. Prove a coherent mathematical unit; include the q=1, small-prime, zero, support, and endpoint cases relevant to that unit.
4. Build all project imports and audit every named theorem's transitive axioms.
5. Use exact finite experiments when they can expose an error. Record their range and arithmetic; never count them as an unbounded proof.
6. Update the status, proof specification, and continuation note; save the checkpoint before proceeding to the next substantial unit.

The current branch does not contain unfinished Lean proof stubs. Open targets live in the blueprint. No main theorem is counted as proved until its precise statement and every input have been connected,

with any deep external hypotheses displayed in the final theorem.

Euler_Product.md

Corrected progression Euler product: checked proof specification

Checkpoint 07 update: the user has supplied the corrected Lemma 3.14. It matches this checked statement; the earlier statement issues are resolved for that revision. The full archived source remains unchanged. See `docs/SOURCE_UPDATE_07.md`. The proof below is the completed checkpoint 06 proof.

Checkpoint 06, 22 October 2026. Source: the locked `sources/current/Draft5.tex`, Lemma 3.14, label `l:motamakemajorprimesquareprog`, equation `e:corupss`. Its SHA256 remains `d2c31b96cb15b00feac09ed4fd9a2b0482726c719c4b772320c0711875d04660`.

The complete Euler-product identity is proved with **Q>2 and positive k**. The last vanishing assertion is proved with the necessary restriction **p<Q** on the obstructing prime. The original statement needs these qualifications; it is not counted as proved verbatim. Both missing qualifications have kernel-checked counterexamples. See `docs/SOURCE_FINDINGS_06.md` and the replacement statement in `corrections/Lemma_3_14_Replacement.tex`.

Statement being proved

For q,k positive and b,x arbitrary integers, use exactly the previously formalized exponential sums from Lemma 3.12 and put

$$B(q;k,b,x)=\sum_{a\in A_q}\Upsilon(a,q,b,k)\mathfrak{s}(a,q)e(ax/q).$$

For Q>2, k>=1 and gcd(b,k)=1, the smooth-modulus sum equals

$$\sum_{P^+(q)<Q}B(q;k,b,x)=\mathcal{T}_2\prod_{2<p<Q}E_p(k,b,x),$$

where h=v_2(k),

$$\mathcal{T}_2=\begin{cases}1+(-1)^x, & h=0,\\ 2^{\min(h,3)}\mathbf{1}_{x-b\equiv 1 \pmod{2^{\min(h,3)}}}, & h>0,\end{cases}$$

and the four cases of the odd-prime factor are

$$E_p=\begin{cases}1+(p+1)/(p-1), & p\mid k,\ (\frac{x-b}{p})=1,\\ 0, & p\mid k,\ (\frac{x-b}{p})\neq 1,\\ 1-(p+1)/(p-1)^2, & p\nmid k,\ (\frac{x}{p})=1,\\ 1+1/(p-1), & p\nmid k,\ (\frac{x}{p})\neq 1.\end{cases}$$

A single product of this case-defined factor is the same mathematical formula as the four products in the source: the four conditions partition the odd primes below Q. No condition has been omitted at Legendre-symbol value zero. The formal local definition uses a harmless unused branch for nonprime p.

The vanishing consequence is: if an odd prime **p<Q** divides k and ((x-b)/p) is not 1, the smooth-modulus sum is zero.

1. Open the sums in the useful order

Write g=gcd(q,k), and retain the genuine quadratic Cohen correlation C_q(n)=sum_(u in A_q) c_q(n-u^2), completed in Lemma 3.1. Opening the two exponential sums, then summing over a and next over u, gives the exact identity

$$B(q;k,b,x)=\frac{\phi(k)}{\phi(q)\phi([k,q])}\sum_{\substack{r\in A_q\\ r\equiv b \pmod g}} C_q(x-r).$$

The existing normalized expansion from Lemma 3.12 proves this finite reordering. The new proof explicitly checks x-u^2-r=x-r-u^2. For every multiplicative arithmetic function f, f(lcm(q,k)) f(gcd(q,k))=f(q)f(k). Applying Mathlib's proved identity to f=phi gives phi(lcm(q,k)) phi(g)=phi(q) phi(k), hence

$$B(q;k,b,x)=\frac{\phi(g)}{\phi(q)^2}\sum_{\substack{r\in A_q\\ r\equiv b \pmod g}} C_q(x-r). \qquad (1)$$

All cancelled totients are first proved nonzero. The coefficient is extended by zero at q=0 solely to use natural-number arithmetic-function interfaces; agreement with the actual exponential sum at every positive q is proved.

Formula (1) needs neither coprimality of b and k nor a distribution theorem. This stronger formulation simplifies the support and multiplicativity proofs.

2. Multiplicativity includes the restriction and weight

Let gcd(m,n)=1. Then

$$\gcd(mn,k)=\gcd(m,k)\gcd(n,k),\qquad \gcd(\gcd(m,k),\gcd(n,k))=1.$$

The ring CRT and its checked unit equivalence identify A_(mn) with A_m×A_n. The progression restriction modulo gcd(mn,k) is exactly the conjunction of the two coordinate restrictions. This equivalence is proved through the canonical reduction homomorphisms, rather than postulated.

The already checked identity C_(mn)(z)=C_m(z)C_n(z), with explicit reductions, separates the summand. The two finite unit sums consequently factor. Totient multiplicativity separates phi(gcd(mn,k))/phi(mn)^2 into the corresponding weights at m and n. Thus

$$B(mn;k,b,x)=B(m;k,b,x)B(n;k,b,x).$$

At modulus one the unit group has one element, its character is one and B(1;k,b,x)=1. The proofs include this case and the zero extension.

3. Uniform vanishing gives finite support

For an odd prime p, if p^2 divides q then C_q(n)=0 for every n. If 16 divides q then C_q(n)=0 for every n. These follow from the completed global prime-power factorization of C: one local factor in its product vanishes. The divisibility-to-valuation bridge is formally checked.

Formula (1) therefore proves, for arbitrary b and x,

$$p^2\mid q,\ p>2 \implies B(q;k,b,x)=0,\qquad 16\mid q \implies B(q;k,b,x)=0.$$

This is a statement about all moduli, not just isolated prime powers. Only squarefree odd parts and a power of two of exponent at most three can contribute.

For an integer cutoff Q>=3, choose the convenient bound

$$N_Q = ((Q-1)!)^3.$$

It is not intended as an optimal bound. If every prime divisor of q is below Q and B(q;k,b,x) is nonzero, then q divides N_Q. Indeed, every prime of q divides (Q-1)!, so its exponent in N_Q is at least three, while its exponent in a nonzero coefficient is at most three. Comparing all prime valuations proves the divisibility.

Conversely, every divisor of N_Q has all prime factors below Q. Consequently

$$\sum_{P^+(q)<Q} B(q;k,b,x) = \sum_{q \mid N_Q} B(q;k,b,x). \qquad (2)$$

The formal proof uses `tsum_eq_sum`, with a proof that every summand outside the divisor set is zero. Thus the complex-valued series has finite support; no conditional rearrangement, unproved convergence or analytic input occurs. Smoothness is modeled by the equivalent prime-divisor condition. For q=1, this agrees with the source convention P^+(1)=1 because Q>2. The extension at q=0 contributes zero.

4. The finite divisor Euler product

For a multiplicative function f with f(0)=0 and f(1)=1, the divisor sum is the Dirichlet convolution (f*zeta)(N). Mathlib proves multiplicativity of this convolution. Applying the natural-number prime-power factorization to it, then identifying the divisors of p^a with p^j, 0<=j<=a, yields

$$\sum_{d \mid N} f(d) = \prod_{p \mid N} \left(\sum_{j=0}^{v_p(N)} f(p^j) \right).$$

This argument is formalized in `sum_divisors_multiplicative` and is applied to the actual B. The primes of N_Q are exactly the primes below Q, each with valuation at least three. The previously proved vanishings truncate the odd-prime exponent sums after one, and the exponent sum at two after three. Equation (2) becomes

$$(1 + B(2) + B(4) + B(8)) \prod_{2<p<Q} (1 + B(p)). \qquad (3)$$

This proves the Euler-product step before any explicit local evaluation.

5. Local evaluations

If q divides k and b is a unit modulo q, the restriction in (1) fixes r=b. Thus B(q)=C_q(x-b)/phi(q). If gcd(q,k)=1 the restriction disappears; opening C and applying the ordinary linear Cohen identity gives

$$\sum_{r \in A_q} C_q(x-r) = \mu(q) C_q(x), \qquad B(q) = \mu(q) C_q(x)/\phi(q)^2.$$

For p^a with a>=2 which does not divide k, write gcd(p^a,k)=p^j. If j=0, mu(p^a)=0. If 0<j<a, the gcd and complementary modulus share p, so the completed progression Cohen identity kills the coefficient. This also proves the partial-overlap cases for powers of two. Coprimality of b and k supplies every unit-class hypothesis via divisibility.

For odd primes, insert the completed evaluation C_p(n)=p+1 for Legendre symbol 1, and 1-p otherwise, and use mu(p)=-1 and phi(p)=p-1. Adding 1 to the coefficient gives precisely the four factors E_p displayed above. Nonzero denominators are proved from primality.

6. The 2-adic sum

If v_2(k)=0, only B(2) can contribute and B(2)=(-1)^x. Otherwise the allowed terms are C_(2^a)(x-b)/phi(2^a), for 1<=a<=min(v_2(k),3). The complete signed factors from Lemma 3.1 give

$$\begin{aligned} 1 + C_2(n) &= 2\mathbf{1}_{n \equiv 1 \pmod 2}, \\ 1 + C_2(n) + C_4(n)/2 &= 4\mathbf{1}_{n \equiv 1 \pmod 4}, \\ 1 + C_2(n) + C_4(n)/2 + C_8(n)/4 &= 8\mathbf{1}_{n \equiv 1 \pmod 8}. \end{aligned}$$

The small congruence predicates are checked by Lean's kernel using `decide`; the complex arithmetic and the relation of the residues at 2,4,8 are proved explicitly. This is not `native_decide` or an external numeric oracle. Splitting the valuation of k into 0,1,2,>=3 proves exactly T_2 in the source, including arbitrary negative integer x and b.

7. Real cutoffs and the corrections

For every real Q>2 and integer prime p, p<ceil(Q) if and only if p<Q. Moreover ceil(Q)>=3. Mathlib's proved `Nat.lt_ceil` transports the integer cutoff theorem to every real cutoff Q>2 without changing the included primes.

At Q=2 the literal smooth series is 1. With k=1, b=x=0 the displayed 2-adic factor is 2, so the unqualified identity fails. For the vanishing sentence, Q=3, k=5, b=1, x=4 gives a series equal to 2, while x-b=3 is a nonsquare modulo five. Both assertions are proved in Lean. The corrected obstruction theorem explicitly requires p<Q; the prime then supplies an actual zero factor in (3).

The replacement LaTeX fragment changes only the statement's cutoff, modulus range and final obstruction restriction. It preserves the displayed identity, T_2 formula and labels. The locked authoritative source is unchanged.

Verification and remaining work

All fifteen project modules build. The source scan covers seventeen Lean files and rejects proof placeholders, extra axioms, native_decide and unsafe code. All 120 named project theorems pass the transitive axiom audit, allowing only `propext`, `Classical.choice` and `Quot.sound`.

The independent exact-integer/rational experiment passes 94,208 fixed-modulus cases with 1<=q<=128, 1<=k<=12, all unit b modulo k and 0<=x<=15. It also passes 3,680 finite Euler-product comparisons for integer cutoffs 3 through 7. These experiments use the classical Ramanujan divisor formula; they do not supply the universal support proof or the formal counterexamples.

Three earlier numbered paper lemmas are complete as stated within positive modulus conventions; this checkpoint adds the corrected version of Lemma 3.14. No headline theorem or general-coefficient Corollary 3.16 is complete. No deep analytic theorem has been assumed. The next target is Corollary 3.16; the new multiplicativity, support and finite Euler-product infrastructure should be reused, with the progression coefficient multiplied by its general integer ell.

`Exceptional_Density_Partial_Summation.md`

The source densities, oscillatory integrals and conditional major-arc deduction

Checkpoint 26. This unit specializes the proved Abel identity and quantitative error transport to the manuscript's actual power model. All derivatives, continuity and integrability requirements are discharged. A bound on the genuine unweighted progression prefix remains an explicit hypothesis.

Exact source objects

For an integer N>=1, a real frequency theta and beta>0, write

$$g_\theta(t) = \exp(-2\pi i\theta t^2), \qquad C_{q,r}(x) = \sum_{0\le n\le \lfloor x\rfloor} \mathbf{1}_{n\equiv r \pmod q}\Lambda(n).$$

The Lean prefix includes n=0, whose von Mangoldt coefficient is zero. It includes every prime power. The lower endpoint in the integral is the real number N/2. The corresponding finite sum uses the natural floor N/2, with that correspondence explicitly proved in the Abel calculation. The statements therefore also cover odd N; dyadic N is not required here.

Define the complex progression model and density by

$$H_{q,z,\beta}(t) = \frac{1}{\phi(q)}\left(t - z\frac{t^\beta}{\beta}\right), \qquad D_{q,z,\beta}(t) = \frac{1}{\phi(q)}(1 - zt^{\beta-1}).$$

The new Lean definitions are `progressionPowerModel` and `progressionPowerDensity`. The primitive is `exceptionalPrimitive`. All real quantities are explicitly embedded into the complex numbers where needed. These are actual functions, rather than unspecified model parameters supplied with regularity assumptions.

The normalized oscillatory integral is

$$M_{N,\beta}(\theta) = \frac{1}{N}\int_{N/2}^{N} t^{\beta-1} g_\theta(t)\,dt.$$

`annularOscillatoryModel` initially uses the Bochner integral over (N/2,N]. `annularOscillatoryModel_interval` identifies it with the interval integral in the manuscript's equation e:M. That identity also holds at N=0 with Lean's inverse convention, although subsequent estimates require N>=1. The integral parameter theta is real: the phase is not assumed periodic in theta when t is nonintegral.

Two calibration results are proved. At beta=1 the real power disappears, and at beta=1, theta=0 the model has value exactly 1/2 for N>=1. This checks the annular interval length and the factor 1/N together.

Derivative and integrability

For t>0 and beta>0, Mathlib's derivative of the real power gives

$$\frac{d}{dt}\frac{t^\beta}{\beta} = \frac{\beta t^{\beta-1}}{\beta} = t^{\beta-1}.$$

Positivity of beta justifies cancellation; positivity of t avoids the singularity at zero. Applying the complex embedding, subtraction and constant-multiple derivative rules proves H'=D. Every point in [N/2,N] is positive when N>=1, so this proves all the regularity needed by the previously established integration-by-parts theorem.

Continuity of the real power on this positive interval gives continuity and interval integrability of D. Continuity of both the power and the quadratic phase proves integrability of their product. Integrability is proved before distributing the Bochner integral over subtraction. The calculus only requires beta>0; the manuscript's additional beta<=1 can be imposed when applying it to an exceptional zero.

Distributing the actual density integral then proves

$$\frac{1}{N}\int_{N/2}^{N} g_\theta(t) D_{q,z,\beta}(t)\,dt = \frac{1}{\phi(q)}\left(M_{N,1}(\theta) - zM_{N,\beta}(\theta)\right).$$

This is `progressionPowerDensity_integral`.

Exact residue error and its quantitative bound

Let

$$W_{q,r} = \sum_{\substack{N/2<n\le N\\ n\equiv r \pmod q}} \Lambda(n) g_\theta(n), \qquad E(t) = C_{q,r}(t) - H_{q,z,\beta}(t).$$

The exact identity `annularProgressionPowerModel_error_identity` is

$$\frac{W_{q,r}}{N} - \frac{M_{N,1}(\theta) - zM_{N,\beta}(\theta)}{\phi(q)} = \frac{1}{N}\left(g_\theta(N)E(N) - g_\theta(N/2)E(N/2) - \int_{N/2}^{N} g_\theta'(t)E(t)\,dt\right).$$

There is no assumed residue estimate in this identity. Both endpoint terms and the exact derivative integral are present. All model regularity conditions have been proved for the displayed H and D.

Suppose delta>=0 and, throughout the actual real interval [N/2,N],

$$|C_{q,r}(t) - H_{q,z,\beta}(t)| \le N\delta.$$

The previously proved derivative bound and exact normalization imply

$$\left|\frac{W_{q,r}}{N} - \frac{M_{N,1}(\theta) - zM_{N,\beta}(\theta)}{\phi(q)}\right| \le \delta(2 + 4\pi|\theta|N^2).$$

This is `annularProgressionPowerModel_error_bound`. The term 2 records both endpoints. The N in the raw prefix error cancels against the normalizing 1/N. No derivative or integrability hypothesis remains for the model in this bound.

Gauss sums and the actual annular symbol

Let q>=1, let chi be a complex Dirichlet character modulo q, and let kappa be a complex coefficient. Assume the displayed raw prefix bound holds for every reduced residue r with z=kappa*chi(r), using the same beta, chi, kappa and delta throughout this one interval. Define

$$U(N,q)=\frac{\log q+2\sqrt{N}\log N}{N}.$$

The earlier exact finite residue grouping, proved nonunit contribution bound and Gauss-sum identity now give

$$\begin{aligned}\left|\widehat{\widetilde{A}}_{N,\Lambda}(a/q+\theta)-\left(\mathfrak{s}(a,q)M_{N,1}(\theta)-\mathfrak{s}_{\chi}(a,q)\kappa M_{N,\beta}(\theta)\right)\right|\\ \le U(N,q)+\phi(q)\delta(2+4\pi|\theta|N^2).\end{aligned}$$

This is `annularMangoldt_majorArc_from_prefix_bound`. Its symbol is the actual finite von Mangoldt annular Fourier sum, not an abstract surrogate. The Gauss sums use the manuscript's negative phase and division by phi(q). The proof sums the per-residue errors over exactly phi(q) units. The nonunit error U(N,q) is already proved for the actual coefficients.

Taking kappa=0 omits the exceptional term; taking kappa=1 includes it. `annularMangoldt_ordinary_from_prefix_bound` separately gives the ordinary case directly from a prefix bound around t/phi(q), with no exceptional parameter in the statement. The deduction does not require primitivity of chi or coprimality of a and q; a published analytic input may impose those additional hypotheses. Exceptional data may change with N. The theorem makes no claim that the same data work at different scales.

Source correspondence and remaining analytic work

This verifies the power-model differentiation, actual partial summation and Gauss-sum substitution in the proof of Lemma 6.5, after equation e:M. It does not prove or silently assume the manuscript's raw progression distribution estimate. To use a published theorem as an explicit deep input, its primary-source statement, range, exceptional data and uniformity must first be matched to the displayed prefix hypothesis.

The final conversion to O(R^-5), with the stated N,Q,R range and choice of constants, remains open. The independent prime-square minor-arc estimate also remains open. Thus full Lemma 6.5, Proposition 4.19 and the headline applications are not marked complete. No new PNT bridge, Siegel-Walfisz theorem or Landau-Page theorem is asserted here.

Files

Module	New named theorems	Result
ExceptionalProgressionDensity.lean	12	Actual model derivative, continuity and integrability, source interval identity, normalization and density integral
PrimeSquarePartialSummation.lean	4	Exact source-model error, quantitative residue bound and conditional ordinary/exceptional major-arc deductions

No numerical experiment is used to justify these analytic statements. They are checked Lean proofs with the raw prefix-error bound displayed as a hypothesis where it is needed.

<!-- checkpoint-verification -->

Verification

All 90 project modules and the root were freshly rebuilt: 3605 jobs pass without warnings/errors. All 739 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 92 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains

two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Finite_Major_Arc_Model_Split.md`

Finite major-arc symbols and the exact high-low split

For a finite rational center set Gamma, the module uses the actual reduced numerator and denominator of each center r. It defines

$$P_r(\xi) = \mathfrak{s}(r_{\mathrm{num}}, r_{\mathrm{den}}) M_N^1(\xi - r), \qquad X_r(\xi) = -\mathfrak{s}_{\chi_r}(r_{\mathrm{num}}, r_{\mathrm{den}}) \kappa_r M_N^\beta(\xi - r).$$

One beta and one family of character/coefficient data are shared over Gamma. The broad model term is $(P_r + X_r)\eta_{\log_2(r_{\mathrm{den}})}(\xi - r)$, and V is their finite sum. Its equality to the previously defined localized genuine Gauss model is proved.

The ordinary low term uses the cutoff $\eta((qN^2/Q)(\xi - r))$ when q<=Q. Its high complement uses broad-minus-narrow in that case and the full broad term otherwise. The exceptional terms use $\eta((B_0(q/q_0)N^2/Q)(\xi - r))$, with selection $q/q_0 \le Q/B_0$. For the source application, the coefficient kappa vanishes when q0 does not divide q, and q/q0 is the source d. The algebra is valid for the broader parameter family without asserting the existence of source exceptional data.

Splitting the ordinary and exceptional cutoff cases gives, exactly,

$$\mathrm{Low} + \mathrm{High} = V, \qquad \widehat{\widetilde{A}}_{N,\Lambda} = \mathrm{Low} + \mathrm{High} + (\widehat{\widetilde{A}}_{N,\Lambda} - V).$$

The error here is the difference from the actual annular von Mangoldt symbol, including prime powers.

Module	New named theorems
FiniteMajorArcModels.lean	5

Scope

These are real-frequency finite symbols and exact identities. The selected finite center set remains an argument. No global periodization or analytic norm estimate is claimed by defining the error as a difference. The full approximation, low/high operator estimates, minor-arc bridge and Theorem 1.1 remain open.

<!-- checkpoint-verification -->

Verification

All 104 project modules and the root were freshly rebuilt: 3623 jobs pass without warnings/errors. All 823 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 106 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Finite_Overlap_and_Major_Arc_Error.md`

Finite overlap and the genuine major-arc model error

This checkpoint combines actual finite rational-center symbols, genuine Gauss sums, the normalized annular integrals, and the constructed smooth cutoff. It proves a major-arc error estimate while preserving the unresolved minor-arc and global-model obligations.

Counting all active scales

For a canonical center $r \in [0,1)$, a reduced denominator below four forces

$$r \in \{0, \tfrac{1}{2}, \tfrac{1}{3}, \tfrac{2}{3}\}.$$

This is an exact rational proof, not a numerical probe. The first two dyadic scales therefore contribute at most four active centers. For larger scales, the previously proved support separation makes the map $r \mapsto \lfloor \log_2 \operatorname{den}(r) \rfloor$ injective on active centers.

If every denominator in a finite canonical center set Gamma is at most M, the total active count is at most $\lfloor \log_2 M \rfloor + 5$. With denominators at most a real $R \geq 1$, a proved floor/log comparison gives

$$\#\{\text{active centers}\} \leq 5 + \frac{\log R}{\log 2}.$$

The finite-norm theorem first removes all inactive terms exactly and only then applies this count.

Geometry of the selected major arc

For $N > 0, R > 0$, rational arcs of denominators at most R and radii $R/(qN^2)$ are disjoint under the explicit sufficient condition

$$2R^3 < N^2.$$

Hence every other center lies outside its own major arc. The actual dyadic cutoff at the chosen center equals one under

$$2R^4 \leq N^2.$$

The real rational center plus its real offset is proved to equal the target circle frequency after coercion, retaining the true negative-phase annular symbol.

Bounding the actual error

Let $C_G > 0$ be one unconditional constant selected from the already proved uniform Gauss-model theorem. It is uniform in N, modulus, character, unit coefficient and allowed exceptional coefficient. Assume $N \geq 2,\ 0 < \beta \leq 1,\ |\kappa_r| \leq 1$, one shared character/coefficient family, and Gamma contained in [0,1) with denominators at most R.

At a selected $r_0 \in \Gamma$, put $q_* = \operatorname{den}(r_0)$, $\theta = \xi - r_0$, and assume

$$|\theta| \leq R/(q_* N^2).$$

The raw progression-prefix estimate is the same explicit hypothesis used in the earlier major-arc proof:

$$\left|\Psi_{q_*,u}(t) - H_{q_*,\kappa_{r_0}\chi_{r_0}(u),\beta}(t)\right| \leq NCe^{-c\sqrt{\log N}}, \qquad N/2 \leq t \leq N.$$

The theorem also retains the earlier explicit parameter budgets $\log R \leq \log N$, $R^5 \log N \leq \sqrt{N}$, and $7 \log R \leq c\sqrt{\log N}$, together with the geometry conditions above.

Removing the chosen center exactly, applying its cutoff core identity, and bounding all remaining model terms gives

$$\left|\widehat{\widetilde{A}}_{N,\Lambda}(\xi) - V_\Gamma(\xi)\right| \leq \frac{4 + (2+4\pi)C}{R^5} + \left(5 + \frac{\log R}{\log 2}\right)\frac{4C_G}{\pi} R^{-5/12}.$$

This is a proved bound for the actual von Mangoldt symbol, including prime powers. Its analytic caller consumes the raw prefix estimate; the paper's own minor-arc lemma is not an assumption.

For every fixed C>=0, the complete displayed right-hand side is also proved eventually at most $R^{-1/6}$. The prior checkpoint provides the source-scale conversion of that rate to $Q^{-1/2}(1+\log N)^{-A}$.

Module	New named theorems
RationalArcOverlap.lean	6
MajorArcGeometry.lean	4
MajorArcModelError.lean	7

Scope and next obligations

The raw progression estimate remains an explicit deep input. No existence theorem for one uniform choice of exceptional data is registered. Gamma is an explicit finite center set; this checkpoint does not construct the global source center set or identify a periodized model on the circle. In particular, the real integral with noninteger integration variable is not silently treated as periodic.

The full-range minor-arc deduction, global approximation 6.9, low 6.14, multifrequency 6.16, high/maximal 6.21, Proposition 4.19 and Theorem 1.1 remain open. The frozen manuscript and accepted revisions are unchanged. These open proof obligations do not establish a counterexample or prescribe a manuscript correction.

<!-- checkpoint-verification -->

Verification

All 108 project modules and the root were freshly rebuilt: 3627 jobs pass without warnings/errors. All 845 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 110 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

`General_Euler_Product.md`

Corollary 3.16: checked proof and source correspondence

Checkpoint 08 update: the user has confirmed applying the supplied statement replacement. Its explicit ranges are accepted; no further edit to that supplied statement is requested. The proof below was completed in checkpoint 07. See `docs/SOURCE_UPDATE_08.md`.

Checkpoint 07, 22 October 2026. Source label: `c:generalmajorprimesquareprog`; equations `e:generalcorupss`, `e:generalT2` and `e:fixedqcoefficient`. The archived source is `sources/current/Draft5.tex`, SHA256 `d2c31b96cb15b00feac09ed4fd9a2b0482726c719c4b772320c0711875d04660`.

The identity is proved for every real Q>2, every positive integer k, and all integers ell,b,n satisfying gcd(b,k)=1. There is **no coprimality or nonzero condition on ell**. The actual exponential sums, local counts, normalization, finite support and complete Euler product are connected in Lean.

The corollary should state the same cutoff and modulus conventions now explicit in the user's revised Lemma 3.14. A statement fragment with this opening is in `corrections/Corollary_3_16_Replacement.tex`. Its displayed formulas are unchanged. See `docs/SOURCE_UPDATE_07.md` for the accepted Lemma 3.14 revision and the distinction between the supplied update and the archived full draft.

Definitions and target

For a positive modulus q let A_q be its unit residue classes and set

$$B_\ell(q;k,b,n)=\sum_{a\in A_q}\Upsilon(a\ell,q,b,k)\mathfrak{s}(a,q)e(an/q).$$

The definition `generalCoefficient` uses exactly the existing `upsilon`, `principalSquareSum` and standard complex additive character. It is extended by zero at q=0, solely to use natural-number arithmetic functions. The paper sums over positive q. The extension contributes zero to the formal series.

For each odd prime p define the genuine finite cardinality

$$N_p=\#\{(u,v)\in A_p^2 : u^2+\ell v\equiv n \pmod p,\quad v\equiv b \pmod{(p,k)}\}.$$

The formal definition `primeSolutionCount` is the cardinality of this filtered product of unit groups. Congruence modulo gcd(p,k) is implemented by the canonical reduction homomorphism. Equality in ZMod p implements the first congruence. Its irrelevant value at p=0 is defined as zero.

The target is

$$\sum_{P^+(q)<Q} B_\ell(q;k,b,n) = \mathcal{T}_2(\ell,k,n;b)\prod_{2<p<Q}\frac{p\phi((p,k))}{(p-1)^2}N_p,$$

with exactly the finite 2-adic factor given in the source. Products over an empty prime set have value one. At q=1, the coefficient is one; this endpoint is proved directly, without a prime-factor calculation at a zero modulus.

1. Expand the actual coefficient

Put g=gcd(q,k) and write psi_q for the standard additive character. Opening Upsilon(a*ell) contributes psi_q(-a*ell*v), the square sum contributes psi_q(-a*u^2), and the remaining phase contributes psi_q(a*n). Their product is psi_q(a*(n-u^2-ell*v)). Summing over unit a gives the Ramanujan sum c_q(n-u^2-ell*v). All sums in this step are finite, so their order may be interchanged.

Thus, with

$$R_\ell(q) = \sum_{\substack{u,v\in A_q\\ v\equiv b \pmod g}} c_q(n-u^2-\ell v),$$

the exact source normalization is

$$B_\ell(q) = \frac{\phi(k)}{\phi(q)\phi([k,q])}R_\ell(q).$$

`general_correlation_expansion` checks the phases and signs. `generalCoefficient_fixed_modulus` proves equation `e:fixedqcoefficient`. The scalar identity phi(lcm(q,k))*phi(gcd(q,k))=phi(q)*phi(k), with positive totients when cancelled, gives the equivalent normalization

$$B_\ell(q) = \frac{\phi(g)}{\phi(q)^2}\sum_{\substack{v\in A_q\\ v\equiv b \pmod g}} C_q(n-\ell v), \qquad C_q(t)=\sum_{u\in A_q} c_q(t-u^2).$$

This is `generalCoefficient_as_quadratic`. It also proves that ell=0 causes no difficulty: no inverse of ell and no substitution dividing by ell is used.

2. Multiplicativity

For coprime m and r, the unit CRT identifies A_(mr) with A_m times A_r. The previously proved identity for C_(mr) separates its two coordinates. Reduction maps preserve subtraction, multiplication and integer casts, so n-ell*v becomes the corresponding n-ell*v in each coordinate.

The progression restrictions separate because gcd(m*r,k)=gcd(m,k)*gcd(r,k), and those two gcds are coprime. The totient normalization separates by totient multiplicativity. Consequently

$$B_\ell(mr) = B_\ell(m)B_\ell(r), \qquad B_\ell(1)=1.$$

These statements concern the actual coefficient, established by `scaled_quadratic_filtered_crt`, `generalCoefficient_mul` and `generalCoefficient_one`. Neither b being a unit nor any restriction on ell is needed for this part when k is positive.

3. Prove finite support before forming an Euler product

The completed quadratic Cohen identity implies pointwise C_q(t)=0 for every integer t if an odd prime square divides q or if 16 divides q. Substitution t=n-ell*v transfers this vanishing to B_ell(q), uniformly in every parameter. Thus a nonzero coefficient can only have odd-prime exponents zero or one and exponent at two at most three.

For an integer cutoff Q>=3, put M=((Q-1)!)^3. Every nonzero smooth coefficient has q dividing M. Every divisor of M has all its prime divisors below Q. The formal infinite sum therefore equals the finite divisor sum

$$\sum_{P^+(q)<Q} B_\ell(q) = \sum_{q\mid M} B_\ell(q).$$

This is `smoothGeneralSeries_eq_divisor_sum`. The finite divisor Euler identity `sum_divisors_multiplicative`, already proved in checkpoint 06, then applies. The vanishing rules shorten the exponent sums and yield

$$\sum_{P^+(q)<Q} B_\ell(q) = (1 + B_\ell(2) + B_\ell(4) + B_\ell(8)) \prod_{2<p<Q} (1 + B_\ell(p)).$$

This is `smoothGeneralSeries_euler_product`. No analytic convergence theorem or rearrangement assumption is used.

4. Evaluate each prime factor by an actual pair count

At a prime p, the exponential definition of the Ramanujan sum has already been proved to give c_p(t)=p*1_(t=0)-1. Let M_p be the number of unit pairs satisfying only the progression restriction on v. Opening this formula gives

$$R_\ell(p) = pN_p - M_p.$$

To count M_p there are two cases. If p does not divide k, the gcd is one, so every v is allowed and M_p=(p-1)^2. If p divides k, coprimality of b and k ensures b is a unit modulo p; the condition fixes exactly v=b and leaves p-1 choices for u. In both cases

$$\phi((p,k))M_p = (p-1)^2.$$

The proofs `prime_progression_unit_mass` and `prime_progression_pair_mass` establish this count and use the actual unit-group cardinality phi(p). With w_p=phi((p,k))/(p-1)^2, one obtains

$$1 + B_\ell(p) = 1 + w_p(pN_p - M_p) = pw_pN_p.$$

This is `generalCoefficient_prime_euler_factor`. In particular, zero solution counts, primes dividing ell, ell=0, and n=0 need no separate exclusions.

5. Keep the exact source factor at two

For nu=1,2,3 use the proved fixed-q identity at q=2^nu. The sum 1+B_ell(2)+B_ell(4)+B_ell(8) is exactly

$$1 + \sum_{\nu=1}^{3} \frac{\phi(k)}{\phi(2^\nu)\phi([k,2^\nu])} \sum_{\substack{u,v \in A_{2^\nu} \\ v \equiv b \pmod{(2^\nu,k)}}} c_{2^\nu}(n - u^2 - \ell v).$$

This is the definition `generalTwoEulerFactor`, with the source's exponent range represented by j=0,1,2 and nu=j+1. Its identification with the local coefficient sum is `generalCoefficient_two_euler_factor`. Higher powers have already been proved to vanish. No further assumption on a 2-adic factor is made.

6. Assemble the identity and handle real cutoffs

`general_progression_euler_product` combines the finite product and the local evaluations for integer Q>=3. For any real Q>2, an integer prime satisfies p<Q exactly when p<ceil(Q). Using this equivalence proves `general_progression_euler_product_real`, with precisely the strict prime cutoff in the paper. This includes nonintegral Q and exact prime endpoints.

Two consistency results connect the new definitions to the earlier lemma: `generalCoefficient_one_multiplier` identifies B_1 with the old coefficient at every natural q, and `generalTwoEulerFactor_one_multiplier` identifies its 2-adic factor with the previous closed valuation formula.

Verification and limits

All 18 project modules build with pinned Lean 4.34.1 and Mathlib `d13f23b723b8a846827a245b89c10fc7d3f11612`. The 150 named project theorems, including 30 new declarations, pass the transitive axiom audit: only propext, Classical.choice and Quot.sound occur. There are no proof placeholders or additional mathematical axioms. The source audit scans 20 Lean files.

The separate script `check_general_euler_product.py` passes 109,824 exact fixed-modulus comparisons and 13,728 finite Euler comparisons. The ranges, signed representatives and zero/negative multipliers are recorded in `verification/general-euler-numerical.json`. All arithmetic uses integers and rational Fractions. These are finite experiments, not inputs to Lean.

This finishes the corollary with the stated ranges. It does not complete a headline theorem of the paper or the general character-twisted square sum. No deep analytic result has yet been assumed.

`High_Low_B_Endpoint.md`

Theorem 4.1: the complete B_N endpoint deduction

Checkpoint 13, 22 October 2026.

The B_N conclusion, equation `e:endimprovbn` (4.9), is proved in Lean from the theorem's local estimate and actual operator norm assumptions. This includes the exact logarithmic exponent, dyadic selection, the truncated parameter range, empty admissible ranges and empty input/test sets.

Theorem 4.1 is still partially complete. Its A_N conclusion, the sharp coefficient in `e:cstar`, and the subsequent strong-type interpolation corollary are not asserted by this checkpoint. The prime-square operator estimates supplying the abstract hypotheses are also later obligations.

Source and theorem correspondence

The frozen source is `sources/current/Draft5.tex`. Its saved reference map is `verification/Draft5.aux`.

Item	Stable label	Typeset number	PDF page
Full abstract high--low theorem	`t:improvinggeneral`	4.1	25
Local crude input	`e:bnv`	4.3	26
Low operator norm input	`e:lobn1`	4.4	26
High operator norm input	`e:hibn1`	4.5	26
B_N endpoint conclusion	`e:endimprovbn`	4.9	26
Pairing/balancing estimate	`e:Bbalance`	4.12	26

The preferred scale is the expression labeled `e:Jchoice`. The source's logarithmic conventions are retained exactly:

$$\operatorname{Log} x = 2 + |\log x|, \qquad \operatorname{Log}\operatorname{Log} x = 2 + \log(2 + |\log x|),$$
$$\Phi_{c,\kappa}(x) = \exp\left(c\frac{(\operatorname{Log} x)^{\kappa}}{\operatorname{Log}\operatorname{Log} x}\right).$$

These are `paperLog`, `paperLogLog` and `paperPhi`. The last definition is recorded for the next stage; defining it is not a proof of the A_N estimate. The definitions have harmless total extensions at x=0 in Lean. Empty-set cases are proved separately, with endpoint value zero.

Exact formal statement for the B_N clause

Fix s,r>0, β≥0, γ≥β and C>0. In the paper, s≥1-v and v<1 imply s>0. Let N>0, let K be a complex-valued convolution kernel on the integers, and let I_x be any finite local window. Write

$$(K * \mathbf{1}_F)(x) = \sum_{y\in F} K(x-y), \qquad \langle K * \mathbf{1}_F, \mathbf{1}_G\rangle = \sum_{x\in G}\sum_{y\in F} K(x-y).$$

The formal definitions are `indicatorConvolution` and `restrictedKernelPairing`. Lean also proves that these finite sums equal the corresponding infinite sums with the actual indicator functions and complex conjugation in the second factor.

Assume the local inequality

$$|(K * \mathbf{1}_F)(x)| \le CN^{-v}\|\mathbf{1}_F \mathbf{1}_{I_x}\|_1.$$

For each admissible dyadic J=2^k with

$$2 \le J \le N^{(1-v)/s}/10,$$

assume operators Lo:$\ell^1\to\ell\infty$ and Hi:$\ell^2\to\ell^2$ satisfying the decomposition on indicators and the genuine norm bounds

$$\|Lof\|_\infty \le CN^{-1}J^s(\log J)^\gamma\|f\|_1, \qquad \|Hif\|_2 \le CJ^{-r}(\log J)^\beta\|f\|_2.$$

These are the actual normed spaces `lp` in Mathlib. The proof does not need linearity of the pieces, so the formal input permits a wider class of maps. The decomposition is required only on indicators, since that is all the restricted endpoint uses. The source's full operator decomposition implies these hypotheses directly.

Then a single D>0, depending only on the fixed parameters and C, works for every such N, kernel, local-window family and finite F,G with |F||G|≤N²:

$$\frac{|\langle K * \mathbf{1}_F, \mathbf{1}_G\rangle|}{N} \le D\,\delta^{1-s/(2(s+r))}(\operatorname{Log}\delta)^{\gamma+s(\beta-\gamma)/(s+r)}, \qquad \delta = \frac{|F||G|}{N^2}.$$

This is `highLow_B_endpoint`. The constant is quantified before N, K, the window family and F,G, so the required uniformity is formal. Common interval support of F,G and positivity of K are not needed for this B_N deduction; the paper itself notes the extension to arbitrary finite sets with the stated cardinality product. Those assumptions may have other uses in the remaining theorem and its applications.

The local windows in the source are integer intervals about x. The proof uses only their finite-set interpretation. The exact local indicator is `finiteIndicatorLp (F ∩ I_x) 1`; its norm is proved to be |F∩I_x|.

1. Indicators, actual norms and Cauchy--Schwarz

`finiteIndicatorLp` constructs the indicator as an element of `lp` at any exponent, using its finite support. For positive finite p, Lean proves

$$\|\mathbf{1}_F\|_p = |F|^{1/p}.$$

In particular, the input norms are exactly |F| and √|F| at exponents one and two. Restricting an indicator to I is proved to give the indicator of F∩I. These identities are not left as informal conversions between counts and norms.

For the high output h in genuine ℓ^2, Mathlib's finite-energy bound gives

$$\sum_{x\in G} |h(x)|^2 \le \|h\|_2^2.$$

The checked finite Cauchy--Schwarz inequality then proves

$$\left|\sum_{x\in G} h(x)\right| \le \sqrt{|G|}\,\|h\|_2.$$

The low output is bounded using its actual $\ell\infty$ norm and summing over G. Triangle inequality and the decomposition therefore yield

$$\frac{|\langle K * \mathbf{1}_F, \mathbf{1}_G\rangle|}{N} \le C\left(\delta J^s(\log J)^\gamma + \delta^{1/2}J^{-r}(\log J)^\beta\right).$$

Lean checks the factors of N through

$$\sqrt{\delta} = \frac{\sqrt{|F|}\sqrt{|G|}}{N}, \qquad N > 0.$$

The scalar balancing inequality is derived from these norm inputs; it is not an extra hypothesis in the final operator theorem.

2. The crude estimate, including empty parameter ranges

Apply the local assumption to F={0}. Since |F∩I_x|≤1, this gives

$$|K(z)| \le CN^{-v}.$$

Two finite sums and triangle inequality imply

$$\frac{|\langle K * \mathbf{1}_F, \mathbf{1}_G\rangle|}{N} \le C\delta N^{1-v}.$$

The real-power identity used to normalize this expression is checked for every N>0. In particular, the proof does not request a decomposition at J=2 when the admissible range is empty.

3. Exact balance identities

Put

$$u = s + r, \quad L = \operatorname{Log} \delta, \quad \theta = 1 - \frac{s}{2u}, \quad \tau = \gamma + \frac{s(\beta - \gamma)}{u} = \frac{r\gamma + s\beta}{u},$$
$$T = \delta^{-1/(2u)} L^{(\beta-\gamma)/u}, \qquad E = \delta^{\theta} L^{\tau}.$$

For 0<δ≤1, all bases of real powers are positive, L≥2, θ>0 and τ≥0. Lean proves the exact identities

$$\delta T^s L^\gamma = E, \qquad \delta^{1/2} T^{-r} L^\beta = E.$$

It also proves δ≤E and δT^s≤E. The first follows from θ≤1 and L^τ≥1; the second follows from the first balance identity and L^γ≥1. None of these steps invokes an unproved asymptotic or optimization result.

4. Dyadic rounding that preserves the cutoff

When T≥2, choose a dyadic J rounded down:

$$2 \le J \le T < 2J.$$

Its existence is proved using the Archimedean power lemma. If T is within the admissible range, J remains within that range. An upward rounding can fail this requirement near the cutoff.

Set

$$A = 1 + \frac{1}{2(s + r)}.$$

Because β≤γ and log L≥0,

$$\log T = -\frac{\log \delta}{2u} + \frac{\beta - \gamma}{u} \log L \le \frac{L}{2u} \le AL.$$

Thus log J≤AL, J^s≤T^s and J^(-r)≤2^r T^(-r). As β,γ≥0, the two exact balance identities give

$$\delta J^s (\log J)^\gamma + \delta^{1/2} J^{-r} (\log J)^\beta \le (A^\gamma + 2^r A^\beta) E.$$

This is the entire interior case, with an explicit parameter-dependent constant and the printed logarithmic exponent.

5. Every boundary and fallback case

Write M=N^((1-v)/s)/10 for the upper cutoff.

Situation	Checked choice or estimate	Resulting coefficient multiplying C E
T≥2 and T≤M	Dyadic J≤T<2J	A^γ+2^r A^β
T≥2 and M<T	Crude estimate	10^s
T<2 and 2≤M	J=2	2^s+1
T<2 and M<2	Crude estimate; no admissible scale required	20^s

For the exceeded-cutoff case, raising N^((1-v)/s)<10T to the positive power s gives

$$N^{1-v} \le 10^s T^s.$$

Then the crude bound is at most C10^s δT^s≤C10^s E. The exponent cancellation ((1-v)/s)s=1-v is explicitly checked with s≠0.

For T<2 and admissible J=2, use log 2≤1 for the low term, δ≤E, and 2^(-r)≤T^(-r), (log 2)^β≤L^β for the high term. This yields C(2^s+1)E. This argument also covers preferred scales T<1.

For an empty admissible range M<2, the same cutoff calculation gives N^(1-v)≤20^s. The crude bound is at most C20^s δ≤C20^s E. All positive scales N are covered; there is no unproved sufficiently-large-N exception.

One explicit final choice is therefore

$$D = C\left(A^{\gamma} + 2^{r}A^{\beta} + 10^{s} + 2^{s} + 1 + 20^{s}\right) > 0.$$

No optimal constant is claimed. If F or G is empty, the pairing and density are zero. Since θ>0, the endpoint is zero and the conclusion follows directly, before any use of a logarithm of a positive density.

Lean files and trust boundary

Module	Checked content
`HighLowNotation.lean`	Exact Log/LogLog/Phi definitions, positivity, dyadic rounding down
`HighLowBalance.lean`	Density/log exponents, exact preferred-scale identities, logarithm bound
`HighLowOptimization.lean`	Full scalar optimization with all four range cases and an explicit constant
`HighLowPairing.lean`	Actual finite convolution, finite complex pairings, genuine lp-two energy and Cauchy--Schwarz
`HighLowEndpoint.lean`	Normalizations, local-kernel crude bound, endpoint from indicator-output inputs
`HighLowOperators.lean`	Exact indicator norms, standard infinite-sum identities, operator norm bridge and `highLow_B_endpoint`

The operator norm estimates are the hypotheses of the abstract theorem. This checkpoint proves their implication, rather than asserting them for the prime-square kernels. No own-paper result is replaced by an axiom. There are no extra mathematical axioms or proof placeholders.

The previous eight completed numbered results remain unchanged. Lemma 3.21 still has its two explicit PNT-limit hypotheses. No PNT or Siegel--Walfisz input enters the new B_N argument. This checkpoint does not increase the count of completely proved numbered results, because Theorem 4.1 also has the unproved A_N conclusion.

Verification and exact finite checks

The fresh build checks all 46 project modules. The source audit scans 48 Lean files and the transitive axiom audit covers 372 named project theorems, including the 51 added here. The only permitted foundational axioms are `propext`, `Classical.choice` and `Quot.sound`.

`scripts/check_high_low.py` records zero failures using integer arithmetic and exact fractions:

Check	Cases
Complete scalar optimization, rational subfamily s=r=1, β=γ=0, δ=T^(-4)	56,164
Admissible dyadic scales examined	122,193
Empty admissible ranges	7,979
Preferred scales below two	2,220
Interior-balance cases	14,667
Exceeded-cutoff cases	39,277
Examples where upward rounding exceeds the cutoff	4,071
Actual complex finite-kernel pairings	6,144
Empty input/test-set pairings	378

The kernel tests use six finite kernels with Gaussian-integer coefficients and every pair of subsets of {-2,-1,0,1,2}. They check the decomposition, global high-output square energy, low-output supremum bound, combined pairing bound and crude kernel estimate. Noninterval and empty sets are included. Irrational norm inequalities are tested by squaring with the required sign case, without converting to floating point.

The scalar experiment is explicitly restricted to its rational subfamily; it does not numerically certify general logarithmic exponents. Lean proves the full real-parameter result and its unbounded quantifiers. These finite checks supplement that proof and do not replace it.

Remaining part of Theorem 4.1

The next target is the A_N conclusion with every fixed coefficient larger than

$$\frac{c_1 s}{2^{\kappa}(s+r)^{\kappa+1}}.$$

It requires the actual low/high/error pairing bound, the two density/scale ranges, dyadic Q selection, domination of logarithmic losses by the exact Phi function, and a uniform epsilon formulation of the sharp coefficient. The displayed first-order Q choice should be handled with explicit epsilon margins; uniform comparability of its first two contributions must not be silently assumed. The subsequent interpolation corollary also remains open.

`High_Low_Theorem.md`

Theorem 4.1: complete restricted endpoint deduction

Current checkpoint 20: the full abstract Corollary 4.15 is complete, including strong interior interpolation and p=2. This document records an earlier stage; see Strong_Improving_Complete.md for the completed proof and current scope.

Checkpoint 15 completes both restricted endpoint conclusions of Theorem 4.1, `t:improvinggeneral`, from its abstract operator norm hypotheses. The main Lean declaration is `PrimeSquares.highLow_AB_endpoint` in `PrimeSquares/HighLowTheorem.lean`.

The source conclusions are equation 4.9 (`e:endimprovbn`), equation 4.10 (`e:endimprovan`) and the coefficient in equation 4.11 (`e:cstar`). The epsilon interpretation of the coefficient is included. Theorem 4.1 is now counted as a complete numbered result. The prime-square estimates that supply its abstract hypotheses and the following interpolation corollary remain open.

Exact conclusion

Let delta=|F||G|/N^2. One DB>0 and one DA>0, chosen before N, both kernels, local windows and F,G, satisfy

$$\frac{|\langle B_N 1_F, 1_G\rangle|}{N} \le D_B \delta^{1-\frac{s}{2(s+r)}} (\operatorname{Log}\delta)^{\gamma+\frac{s(\beta-\gamma)}{s+r}},$$

and

$$\frac{|\langle A_N 1_F, 1_G\rangle|}{N} \le D_A \delta^{1-\frac{s}{2(s+r)}} \Phi_{cstar,\kappa}(\delta)$$

for every fixed

$$cstar > \frac{c_1 s}{2^\kappa (s+r)^{\kappa+1}}.$$

The proof includes all positive real N and all finite F,G in the integers with |F||G|<=N^2, including empty sets and sets outside a common interval. It therefore includes the paper's positive integer scales and its concluding arbitrary-finite-set extension. The exact definitions `Log x=2+abs(log x)` and `LogLog x=2+log(Log x)` are retained.

The finite convolution sum is defined with the source orientation x-y, and the pairing is formally identified with the ordinary infinite sum against the conjugate indicator in `restrictedKernelPairing_as_tsum`. Finite sums are not used as a substitute for a different pairing.

Source hypotheses and Lean correspondence

`HighLowEndpointInputs` collects only the indicator restrictions of the source assumptions. Its operator norm fields use genuine Mathlib lp spaces.

Source	Lean field or declaration	Exact restriction used
Positive B_N convolution kernel	`nonnegative`, `NonnegativeKernel`	Every kernel value has imaginary part zero and nonnegative real part
Equation 4.2, `e:anbnsupbound`	`domination`	Norm of A_N applied to any finite indicator is at most `(log N)^a` times the real part of B_N applied to that indicator
Equation 4.3, `e:bnv`	`local_bound`	The stated local l1 norm on a finite window, for all finite indicators
`e:lobn1`, `e:hibn1`	`B_decomposition`, `OperatorHighLowBound`	Genuine l1-to-linfinity and l2-to-l2 maps at every admissible dyadic J
`e:decompan--e:errorgeneral`	`A_decomposition`, `OperatorOrliczBound`	Genuine l1-to-linfinity and two l2-to-l2 maps at every admissible dyadic Q

The final theorem assumes v<1, 1-v<=s, r>0, 0<=beta<=gamma, a>=0, c0,c1,c>0, 0<kappa<1, and the strict coefficient inequality. These include the printed parameter ranges. The printed requirements v>=0 and alpha>0 can be omitted for this deduction. Only the positivity of B_N is used; the A_N kernel may be complex. Linearity and convolution formulas for the individual decomposition pieces are unnecessary once their actual norm bounds and indicator decomposition identities are given. These are relaxations of source hypotheses, with no additional hypothesis introduced.

The local windows are arbitrary finite sets in the formal theorem. The source intervals give a particular choice. No claim is made that the prime-square kernels satisfy these hypotheses merely because the abstract implication has been proved.

Separate three-piece constants and error input

The A_N predicate retains three separate real constants CLo, CHi, CErr:

$$\begin{aligned}\|\mathrm{Low} f\|_\infty &\le C_{Lo} N^{-1} Q^s (\log Q)^\alpha \|f\|_1,\\ \|\mathrm{High} f\|_2 &\le C_{Hi} Q^{-r} \exp\left(c_1 \frac{(\log Q)^\kappa}{\log\log Q}\right)\|f\|_2,\\ \|Ef\|_2 &\le C_{Err} Q^{-r} (\log Q)^M (1+\log N)^{-1}\|f\|_2.\end{aligned}$$

The exponent M and the norm constant CErr are distinct fixed parameters. The source provides every A>0; the proof uses its permitted value A=1, with the associated power M=C_1. Thus it requires a consequence of the source error hypothesis. The bound at every positive A is not assumed as an unproved analytic statement within this abstract theorem; it is a given operator hypothesis of the source, restricted to one value.

To use the scalar bound, the proof forms

$$C_A = 1 + |C_{Lo}| + |C_{Hi}| + |C_{Err}|.$$

It proves that this number is positive and majorizes the three constants. Every multiplier multiplying a constant is checked to be nonnegative before it is enlarged. All constants and the power M are fixed before N and Q. The notation C_A here denotes this auxiliary common constant; it is not an identification of the source's error exponent with a norm constant.

Actual operator-to-pairing bridge

`finiteIndicatorLp` is a genuine element of lp, with checked identities

$$\|1_F\|_1 = |F|, \qquad \|1_F\|_2 = \sqrt{|F|}.$$

The three output functions for an indicator are a bounded low function and two actual l2 functions. Triangle inequality and the proved finite l2 Cauchy--Schwarz estimate give

$$|\langle A_N 1_F, 1_G\rangle| \le |G|\|\mathrm{Low} 1_F\|_\infty + (\|\mathrm{High} 1_F\|_2 + \|E1_F\|_2)\sqrt{|G|}.$$

The input norm identities and exact normalization by N then yield

$$\begin{aligned}\frac{|\langle A_N 1_F, 1_G\rangle|}{N} \le C_A\Bigg[&\delta Q^s (\log Q)^\alpha + \delta^{1/2} Q^{-r} \exp\left(c_1 \frac{(\log Q)^\kappa}{\log\log Q}\right)\\ &+ \delta^{1/2} Q^{-r} (\log Q)^M (1+\log N)^{-1}\Bigg].\end{aligned}$$

This is `restrictedKernelPairing_orlicz_bound`, deduced from actual output norms. The final theorem does not take this paper-specific scalar pairing bound as a hypothesis.

Positive-kernel pairing domination

For a nonnegative B_N kernel, every B_N indicator output is real and nonnegative. Consequently its finite pairing equals the sum of those nonnegative real outputs, and its norm equals that same sum. This identity is proved in `restrictedKernelPairing_norm_positive`.

Summing the source pointwise domination and using triangle inequality gives

$$|\langle A_N 1_F, 1_G\rangle| \le (\log N)^a |\langle B_N 1_F, 1_G\rangle|.$$

The normalized identity is `restrictedKernelPairing_domination_normalized`. It accounts explicitly for the positivity needed to pass from pointwise domination to a norm of the B_N pairing. The completed B_N endpoint from checkpoint 13 is then applicable.

Uniform scalar optimization: every density range

Set u=s+r, k=1/(2u), L=Log(delta) and W(L)=L^kappa/(2+log L). Checkpoint 14 proved the actual dyadic balancing bound with every coefficient above the printed leading one. The full scalar implication, including the remaining ranges, is now `orlicz_scalar_endpoint`.

The proof chooses

$$d = \frac{c_0}{k + 1 + \log 4} > 0.$$

It proves d<=c0/(k+1). It also proves the following useful implication: if L>=2 and L<=d*t, then log4<=c0*t. This is an elementary multiplication by a positive denominator, checked in `orlicz_small_cutoff`.

There are three cases:

1. **Complementary range:** d*(log N)^c<=L. Positive domination and the B_N endpoint bound the A_N pairing by a fixed constant times `(log N)^a*delta^theta*L^tau`. The already proved uniform logarithmic absorption `log_density_domination_le_orlicz` bounds this by `D*delta^theta*Phi(cstar,kappa,delta)` over the entire density interval.
2. **Large L in the other range:** L>T, or L>=T at the chosen threshold, and L<=d*(log N)^c. The earlier constructed dyadic scale is admissible since d<=c0/(k+1), and its three scalar contributions have the required bound. The actual error decay factor is included.
3. **Bounded L in the other range:** L<T and L<=d*(log N)^c. The special choice of d proves that the fixed dyadic Q=4 is admissible. For theta=1-s/(2u)<=1 the proof checks `delta<=delta^theta` and `sqrt(delta)<=exp(T)*delta^theta`. These follow from 0<delta<=1 and L<=T. Substitution at Q=4 gives a fixed multiple of delta^theta; Phi>=1 completes the estimate.

An empty admissible Q range is covered by the first case: either remaining case entails an admissible Q, as proved. No decomposition at an inadmissible scale is invoked. The low/high/error terms include their separate constants through C_A, and their common endpoint constant is selected before N,delta.

One valid unoptimized scalar constant is

$$D_A = D_B D_C + 3C_A + C_A C_{\mathrm{compact}},$$

where D_C is the uniform complementary-range absorption constant and C_compact is the explicitly defined fixed-Q coefficient in `orliczCompactConstant`. The density threshold T depends only on the fixed parameters, alpha and M. Its dependence is permitted and never involves N, F or G.

The sharp asymptotic step uses the strict-margin scale `log Q approximately kL+bW(L)`, with `c1*k^kappa/(s+r)<b<cstar/s`. It proves the literal log(log Q) scaling and rounding limits. The particular first-order expansion in `e:Qchoice` is not formalized; the epsilon-margin construction proves the same endpoint conclusion directly. See `blueprint/Orlicz_A_Scalar_Balance.md` for that step.

Small scales, zero density and uniformity

The operator bridge's growth and error-decay inequalities use N>=1. For nonempty F and G, their cardinalities are positive integers and `1<=|F||G|<=N^2`. If N>0, this implies N>=1. This deduction is proved in the final theorem. Thus every smaller positive N already has an empty F or G.

If either set is empty, the actual pairing vanishes. Since `theta=1-s/(2(s+r))>0`, the density factor at zero vanishes too. These cases are handled before applying any positive-density scalar result. In particular, no logarithm at a zero density is used in a limit argument. The total Lean extensions of Log and Phi cause no ambiguity in the zero endpoint.

Verification and numerical scope

Checkpoint 15 adds four modules and 18 named theorems. The whole project has 54 modules and 424 named theorem declarations. Every module and the root receive a fresh build with the artifact cache disabled, passing 3451 jobs. The complete source scan covers 56 Lean files. Every named theorem receives a transitive axiom audit with exactly the whitelist propext, Classical.choice and Quot.sound. See the current verification logs.

The new independent exact finite experiment checks 6144 actual complex convolution pairings, including 378 empty pairs, the three-piece norm bound, positive-kernel identities, 18432 domination cases, 110592 normalized domination cases, and 13104 normalization identities with separate constants. Square-root sums are certified by integer isolating intervals with exact equality detection; no floating-point arithmetic is used. The report and reproducible script are `verification/three-piece-pairing-numerical.json` and `scripts/check_three_piece_pairing.py`.

These numerical checks concern finite pairing components. They do not test the unbounded analytic optimization, all-scale operator hypotheses or the sharp coefficient; those implications are established by Lean. No external analytic input, PNT or new mathematical axiom is used in Theorem 4.1.

Status and next dependency

The nine unconditional completed numbered results are 3.1, 3.11, 3.12, accepted revised 3.14, accepted revised Corollary 3.16, and original 3.20, 3.24, 3.27 and Theorem 4.1. Lemma 3.21 keeps its explicit two PNT-limit hypotheses. The full archived sources and accepted revision fragments are unchanged. No new manuscript statement correction is required by this proof.

Next is Corollary 4.15 (`c:improvinggeneral`): deduce the strong lp-improving bound from the restricted endpoints and uniform l2 bounds. That interpolation argument remains an open obligation; no strong lp or prime-square main theorem is claimed here.

`Integer_Fourier_and_Multipliers.md`

Integer Fourier transform and the actual square multipliers

Checkpoint 22. Source: Draft5, equations `e:basicaverages` and `e:tildedef2`, and the Fourier framework preceding Lemma 6.5. This unit connects the completed actual averaging operators to Mathlib's genuine Plancherel theory. It supplies prerequisites for Proposition 4.19; it does not prove its major-arc, low, high, error or maximal estimates.

Exact conventions

Let T = R/Z with Haar measure of total mass one. Put

$$c_n(\theta) = \exp(-2\pi i n\theta), \qquad n \in \mathbb{Z}.$$

Mathlib's `fourier n` uses the positive phase. We explicitly define `negativeFourierCharacter n = fourier (-n)` at period one. The theorem `negativeFourierCharacter_real` proves the displayed exponential formula for every real lift theta. The character product law and unit magnitude are proved without restricting theta to rational frequencies.

The measure is `AddCircle.haarAddCircle`, not an unspecified volume normalization. Elements of circle L2 are equivalence classes modulo almost-everywhere equality. All formulas involving their chosen representatives are correctly stated almost everywhere.

The actual unitary transform

Mathlib proves that its Fourier monomials form an orthonormal Hilbert basis. Negation is a bijection on the integers, so the family c_n has the same orthonormality and the same dense span. We prove these facts and construct `negativeFourierBasis` using `HilbertBasis.mk`.

Inverting the basis representation defines the complex-linear isometric equivalence

$$\mathcal{F} : \ell^2(\mathbb{Z};\mathbb{C}) \simeq L^2(T;\mathbb{C}).$$

Consequently, for every actual l2 sequence f, rather than only finite inputs,

$$\|\mathcal{F} f\|_2 = \|f\|_2.$$

This is `integerFourier_norm`. The inverse is part of the constructed isometric equivalence; `integerFourier_inverse` records one inverse identity. No Plancherel assumption, postulate or finite-grid approximation is used. The pinned Mathlib supplies the underlying density and Hilbert space arguments.

The inverse coefficients have the required positive inverse phase:

$$(\mathcal{F}^{-1}g)(n) = \text{fourierCoeff}(g)(-n) = \int_T e(n\theta)g(\theta)\,d\theta.$$

`integerFourier_coefficient` proves the coefficient identity, using the actual Mathlib coefficient definition and the reflected Hilbert basis.

For the finite sequence supported on F with coefficients f(n), we prove

$$\mathcal{F}\left(\sum_{n\in F} f(n)\delta_n\right) = \left[\theta \mapsto \sum_{n\in F} f(n)e(-n\theta)\right]_{L^2}.$$

This is `integerFourier_finiteInput`. The continuous polynomial's exact real-lift formula is `finiteFourierPolynomial_real`; its squared L2 norm is exactly the finite sum of |f(n)|^2, by `finiteFourierPolynomial_parseval`. Empty support and zero coefficients are included.

Continuous symbols and all-input operator bounds

For a continuous symbol m on T, the product m g is in circle L2 for every g in circle L2, since

$$|m(\theta)g(\theta)| \le \|m\|_\infty |g(\theta)|.$$

We prove membership, representative compatibility, complex linearity and continuity, constructing `circleMultiply m`. Define

$$U_m = \mathcal{F}^{-1}\ \text{Mul}_m\ \mathcal{F}.$$

`integerMultiplier m` is this actual continuous complex-linear map on integer l2. We prove

$$\|U_m\| \le \|m\|_\infty, \qquad \mathcal{F}(U_m f) = m\mathcal{F}f \quad \text{a.e.}$$

The operator bound holds for every l2 input. Addition, scalar multiplication, zero, negation and subtraction of symbols have the exact corresponding operator identities. In particular, if B >= 0 and |m(theta)-v(theta)| <= B for every theta, then

$$\|U_m - U_v\|_{\ell^2\to\ell^2} \le B.$$

`integerMultiplier_error_bound` proves this implication. The uniform symbol inequality is an explicit hypothesis of that transport lemma. It is not an assertion that the paper's proposed approximation already satisfies it. This unit treats continuous symbols; it makes no claim to have implemented every bounded measurable multiplier or a maximal multiplier theorem.

Translations and weighted square sums

Let tau_d f(x) = f(x-d). First we prove exactly

$$\tau_d\delta_n = \delta_{n+d}.$$

Multiplying c_n by c_d gives c_{n+d}. The transform identity therefore holds on every single-coordinate input. Equality of continuous linear maps follows from density of finite-support l2 sequences, via `lp.ext_continuousLinearMap`. Thus

$$\tau_d = U_{c_d}, \qquad \mathcal{F}(\tau_d f)(\theta) = e(-d\theta)\mathcal{F}f(\theta) \quad \text{a.e.}$$

The equality is `integerTranslate_l2_multiplier`, and the representative formula is `integerFourier_translate_ae`. This step checks the sign against the actual translation definition; it does not change that definition to fit a desired multiplier.

For any finite set S of natural numbers, real scalar c and real weights w, put

$$T_{S,c,w}f(x) = c\sum_{n\in S} w(n)f(x-n^2), \qquad m_{S,c,w}(\theta) = c\sum_{n\in S} w(n)e(-n^2\theta).$$

`finiteSquareSymbol_real` proves this symbol's real-lift formula, and `finiteSquareOperator_l2_multiplier` proves

$$T_{S,c,w} = U_{m_{S,c,w}}.$$

Finite linear combinations of the proved translation identities give this equality. It holds on all of integer l2, for arbitrary signs of c and w, including empty S. No distribution-of-primes input is involved.

The full and annular symbols specialize to

$$\widehat{A}_{N,w}(\theta) = \frac{1}{N}\sum_{0<n\le N} w(n)e(-n^2\theta), \qquad \widehat{\widetilde{A}}_{N,w}(\theta) = \frac{1}{N}\sum_{\lfloor N/2\rfloor<n\le N} w(n)e(-n^2\theta).$$

The exact operator equalities are `weightedSquareAverage_l2_multiplier` and `annularWeightedSquareAverage_l2_multiplier`. The two von Mangoldt real-lift formulas explicitly use `ArithmeticFunction.vonMangoldt`. Every prime power remains in the sum. The formal definitions also cover N=0, using Lean's total inverse 0^-1=0; the source application uses positive dyadic N.

The theorem `annularWeightedSquareAverage_fourier_error_bound` now turns any future proved uniform error estimate for the actual annular symbol into the same l2 operator bound. The hard estimate itself remains open.

Inverse kernels and convolution agreement

For a continuous m, define the genuine l2 sequence

$$K_m = \mathcal{F}^{-1}[m]_{L^2}.$$

`fourierKernel_coefficient` identifies K_m(x) with the actual coefficient `fourierCoeff m (-x)`. Using the already proved translation identity, commutativity of symbol multiplication gives

$$U_m(z\delta_i)(x) = K_m(x-i)z.$$

Finite summation then proves

$$U_m\left(\sum_{i\in F} f(i)\delta_i\right)(x) = \sum_{i\in F} K_m(x-i)f(i)$$

for every finite F, every complex coefficient function f and every integer x. These are actual pointwise integer-sequence equalities, not just circle a.e. statements. They supply `KernelL2Bound K_m ||m||` and its version with any proved uniform bound B. For the finite square symbol, the new inverse kernel is proved equal at every integer to the original `finiteSquareKernel`. Thus both constructions agree exactly.

A general smooth-cutoff inverse kernel need not have the original averaging kernel's compact support. No positivity, compact support or absolute summability is inferred for general K_m by this unit.

Rational frequencies and the earlier Gauss sums

For every positive modulus q and all integer a,n, we prove

$$c_n(a/q) = \mathrm{stdAddChar}_q(-an).$$

The squared version gives

$$e(-an^2/q) = \mathrm{stdAddChar}_q(-an^2).$$

These are `negativeFourierCharacter_rational` and `negativeSquareCharacter_rational`. The proof uses the actual complex exponential definitions, without a coprimality restriction on a.

The earlier principal and twisted quadratic sums therefore equal, respectively,

$$\frac{1}{\varphi(q)}\sum_{u\in(\mathbb{Z}/q\mathbb{Z})^\times} c_{\widetilde{u^2}}(a/q), \qquad \frac{1}{\varphi(q)}\sum_{u\in(\mathbb{Z}/q\mathbb{Z})^\times} \chi(u)c_{\widetilde{u^2}}(a/q),$$

where tilde u is the standard natural representative. Both identities are formally proved, for arbitrary complex Dirichlet characters in the twisted case, and include q=1. They connect the arithmetic modules' minus sign and totient normalization to the analytic symbols.

Files and verification scope

Module	New named theorems	Result
CircleFourier.lean	15	Reflected Hilbert basis, actual unitary transform, finite formulas and Parseval
CircleMultipliers.lean	21	Actual all-input multiplier maps, norm bounds and linear identities
SquareFourier.lean	16	Exact translations, full/annular square symbols and error-bound transport
FourierKernels.lean	9	Actual inverse kernels, finite convolution and genuine kernel l2 bounds
FourierGaussCompatibility.lean	4	Rational phase, principal and twisted normalization compatibility

The five modules add 65 named theorems, for 678 in the whole project. The total includes supporting lemmas; it is not a count of completed numbered paper statements. Every module is root-imported and every named theorem is included exactly once in the transitive axiom audit.

The full fresh artifact-cache-disabled build passes 3595 jobs, including every one of the 80 project modules and the root, with no warnings/errors. All 678 named project theorems pass the complete transitive whitelist: propext, Classical.choice and Quot.sound. The source scan checks 82 Lean files and finds no placeholders or extra mathematical axioms. Lean 4.34.1 and Mathlib d13f23b723b8a846827a245b89c10fc7d3f11612 remain pinned.

Independent finite probes

`scripts/check_fourier_conventions.py` uses exact Gaussian rationals and formal independent log(prime) symbols. It checks 532 translations, 2856 actual finite square multiplier identities, 189 dyadic symbol reconstructions, 7 Gauss sign/normalization cases and 27 finite cyclic Parseval cases. The rational frequency denominators are 1,2,4. No floating point or sampling tolerance is used.

At theta=1/4 the explicit diagnostics include

$$\mathcal{F}\delta_1 = -i, \qquad \widehat{A}_{4,1} = (1-i)/2, \qquad \widehat{A}_{4,\Lambda} = (2\log 2 - i\log 3)/4.$$

The annular von Mangoldt value is (log2-i log3)/4. Reversing the sign changes -i to +i, and omitting the prime power 4 loses log2/4 from the full symbol. Both mutations are detected. These finite probes do not prove general Plancherel or any asymptotic estimate. The genuine infinite-dimensional bridge is the separate Lean construction above.

What remains before Proposition 4.19

Dependency	Status
Actual averages, positivity, elementary local and uniform lp/l2 bounds	Complete at checkpoint 21
Actual negative-phase Fourier/Plancherel and exact square multipliers	Complete in this unit
Published deep analytic input boundaries	Must be verified and stated before use
Lemma 6.5: actual major-arc prime-square input and paper-specific bookkeeping	Open
Lemma 6.9: actual approximation by V_N	Open
Proposition 6.14: low contribution	Open
Lemma 6.16 and Orlicz prefix estimate	Open
Proposition 6.21: high and maximal high estimates	Open
Proposition 4.19 assembly and Theorem 1.1 application	Open

The next step is Lemma 6.5: exact residue grouping of the actual finite Lambda sum, non-unit and prime-power bookkeeping, partial summation, and consumption of precisely quantified published analytic inputs. Own-paper deductions remain proof obligations. Exceptional conductor, character and beta may vary with N and must not be fixed across scales in later maximal arguments.

The ten completed numbered results remain unchanged. This unit introduces no new deep hypothesis. Lemma 3.21 still has its earlier two explicit PNT limits; their external bridge is not integrated and is not used here. The frozen manuscript and accepted revisions are unchanged.

`Interpolation_Geometry.md`

Corollary 4.15: uniform geometric weights and actual complex block bounds

Current checkpoint 20: the full abstract Corollary 4.15 is complete, including strong interior interpolation and p=2. This document records an earlier stage; see Strong_Improving_Complete.md for the completed proof and current scope.

Checkpoint 19 update: actual rank blocks, coefficient mass and the strong finite bilinear estimate are now proved. See `Rank_Blocks_and_Finite_Bilinear.md`. The remaining-obligation list below records checkpoint 18; output norm duality and final strong operator assembly still remain open.

Checkpoint 18 proves the actual geometric summation estimate needed for strong interpolation, its exact N scaling, and the estimate for any specified finite family of complex convolution blocks. Two modules add 22 named theorems. **The full strong interior estimate in Corollary 4.15 remains open:** the rank partition and its coefficient mass bound, finite duality, and final assembly are still required.

Source and checked scope

Source: Corollary 4.15 (`c:improvinggeneral`), near line 2431 of `sources/current/Draft5.tex`. Equation 4.17, the global restricted estimate, and the strong p=2 case are already proved. The target equation 4.16 is

$$\|A_N f\|_{p'} + \|B_N f\|_{p'} \le C_p N^{1/p'-1/p} \|f\|_p, \qquad p_0 < p \le 2, \qquad p_0 = \frac{2(s+r)}{2r+s}.$$

Fix p0<q<p<2. For one kernel K, the available global restricted bound has constant A, and its genuine continuous l2 realization has norm <=B. Put

$$a = \frac{1}{q} - \frac{1}{p} > 0, \qquad b = \frac{1}{p} - \frac{1}{2} > 0.$$

`interpolation_gaps_pos` proves these strict inequalities. The geometric module works for arbitrary a,b>0 and A,B>=0. No prime distribution input is used by this deduction.

Module	Named theorems	Checked content
`InterpolationGeometry.lean`	15	Actual weights, summability, uniform total sum, actual Schur estimates
`InterpolationBlockBounds.lean`	7	Exact scaling, complex block bound, finite family estimate

The actual summable weight

For X>0 and n>=0, define

$$h_X(n) = \min\left\{ A\left(\frac{2^n}{X}\right)^a, B\left(\frac{2^n}{X}\right)^{-b} \right\}.$$

This is the Lean definition `interpolationWeight`. The proved constant is

$$C(A,B,a,b) = \frac{A}{1-2^{-a}} + \frac{2^b B}{1-2^{-b}}.$$

`interpolationWeightConstant_nonneg` proves C>=0. Both geometric ratios are strictly between zero and one by `dyadic_decay_ratio`.

First, summability itself follows for every X>0 from

$$0 \le h_X(n) \le B X^b (2^{-b})^n.$$

The factorization and comparison are proved, then the checked Mathlib geometric-series theorem gives `interpolationWeight_summable`. This initial majorant depends on X; the next argument removes that dependence.

For X>=1, construct k>=0 with 2^k<=X<2^(k+1), using the checked Archimedean power-selection theorem. For n<k,

$$h_X(n) \le A(2^{-a})^{k-n}.$$

The map n->k-n is injective on {0,...,k-1}. Therefore this finite sum is bounded by the full nonnegative geometric series A/(1-2^(-a)). This argument is checked in `finite_reversed_geometric_sum_le`; truncation of natural subtraction is handled using the explicit range condition.

For the tail, indexed by n+k with n>=0, X<=2*2^k gives

$$h_X(n+k) \le 2^b B(2^{-b})^n.$$

The negative power reverses the ratio comparison, with positivity proved before applying it. Summing the tail yields 2^b*B/(1-2^(-b)). The original convergent series is exactly its finite head plus this shifted tail.

For 0<X<1, take k=0. The head is empty, and X<=2*2^0 supplies the same tail estimate. No assertion 2^k<=X is used in this case.

Thus `interpolationWeight_tsum_le` proves, for every real X>0,

$$\sum_{n\ge 0} h_X(n) \le C(A,B,a,b).$$

The constant contains no X or N. `interpolationWeight_N_squared` gives the actual application X=N^2 for every real N>0, including N<1.

Schur with the actual weights

For any finite index sets S,T, the matrix w(i,j)=h_(N^2)(i+j) has finite row and column sums <=C. The earlier injective-shift lemma bounds each row by the now-proved total series. The finite Schur theorem therefore applies without an additional summability or geometric-bound hypothesis.

`interpolationWeight_finite_schur` proves the coefficient l2 estimate. `interpolationWeight_finite_schur_lp` gives, for 1<=P<=2,

$$\sum_{i\in S, j\in T} h_{N^2}(i+j)c_i d_j \le C\left(\sum_{i\in S}|c_i|^P\right)^{1/P}\left(\sum_{j\in T}|d_j|^P\right)^{1/P}.$$

The formal exponent is ENNReal P, with ordinary value P.toReal. Empty sets, zero weights/constants and signed real coefficients are included.

Exact scale algebra

`interpolation_scale_balance` proves, for N,f,g>0 and arbitrary real x,y,

$$N^{1-2x}f^x g^x = N^{1-2y}f^y g^y\left(\frac{fg}{N^2}\right)^{x-y}.$$

The proof expands the quotient and product powers, then combines powers of positive bases. Specializing f=2^i, g=2^j gives the dyadic identity.

For nonnegative amplitude bounds u,v, put

$$c_i = 2^{i/p}u, \qquad d_j = 2^{j/p}v.$$

The Lean definition `interpolationBlockCoefficient` uses (2^i)^(1/p), and `dyadic_pow_rpow` justifies interchange of the natural and real powers. The restricted and l2 block scalars satisfy the exact identities

$$uvAN^{1-2/q}2^{i/q}2^{j/q} = N^{1-2/p}c_i d_j A\left(\frac{2^{i+j}}{N^2}\right)^a,$$

$$uvB2^{i/2}2^{j/2} = N^{1-2/p}c_i d_j B\left(\frac{2^{i+j}}{N^2}\right)^{-b}.$$

`interpolation_block_min_identity` factors their minimum as N^(1-2/p)*c_i*d_j*h_(N^2)(i+j). Its common factor is nonnegative, including zero amplitudes. The previously proved `holderConjugate_scaling` identifies 1-2/p with the paper's 1/p'-1/p when p>1.

Actual complex convolution blocks and finite families

Suppose |F|<=2^i, |G|<=2^j, |f|<=u on F and |g|<=v on G, with u,v>=0. `finiteKernelPairing_dyadic_block_bound` proves for the actual finite sesquilinear convolution pairing

$$|B_{F,G}(f,g)| \le N^{1-2/p}c_i d_j h_{N^2}(i+j).$$

Its input is the already available restricted indicator bound at q, positivity of K, and a genuine continuous l2 realization with norm <=B. The l2 pairing estimate is derived from that actual operator. Monotonicity of positive powers gives the dyadic cardinality bounds. The checked positive-kernel extension handles all complex phases. The minimum identity above then gives the literal scale factor, without dropping powers of N.

`finite_complex_block_family_bound` sums these actual complex pairings over any specified finite families F_i,G_j with their support-cardinality and amplitude bounds. Triangle inequality and the actual-weight Schur estimate give

$$\left|\sum_{i\in S, j\in T} B_{F_i,G_j}(f_i,g_j)\right| \le N^{1-2/p}C\left(\sum_{i\in S}|c_i|^p\right)^{1/p}\left(\sum_{j\in T}|d_j|^p\right)^{1/p}.$$

The constants depend on A,B,p,q and not on N or the number of blocks. The generic theorem takes the restricted bound and genuine l2 bound as explicit inputs, along with the stated finite block data. The restricted bound is already proved from the paper's abstract high-low inputs in checkpoint 16. No partition or desired coefficient mass estimate is silently supplied.

What remains before closing the corollary

The finite family estimate does not yet compare its coefficient norms with those of arbitrary original inputs. The next steps are:

1. Construct the decreasing-magnitude dyadic rank blocks for every finite complex input, prove coverage/disjointness, and prove sum c_i^p<=3 sum |f|^p, including ties, zero input, and first/last blocks.
2. Identify the original finite bilinear pairing with the sum over these actual blocks and apply `finite_complex_block_family_bound`.
3. Prove finite-output lp norm duality with the correct complex phase, converting the finite bilinear estimate to the finite-input norm bound.
4. Apply the already checked lp realization and exact-constant density transfer, retain the two operators' l2 constants, and assemble the strong interior range with p=2.

Corollary 4.15 remains partial until these connections are complete. Its desired conclusion is not an axiom or external analytic hypothesis.

Verification and finite experiments

All 64 project modules and the root receive a fresh build with the artifact cache disabled: 3461 jobs pass without warnings or errors. All 511 named theorems pass the transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source audit scans 66 Lean files. No new mathematical axiom or deep analytic input is used.

`scripts/check_interpolation_geometry.py` independently checks 2592 finite 96-term geometric sums, enclosing 248832 terms. The six positive exponents include 1/16, and eight N values range from 1/16 to 2^20. Zero constants, N=1 and both sides of that scale are included. Fractional powers have certified rational enclosures of width at most 2^(-40): each root enclosure is checked by exact integer/rational powers. The finite sum is bounded from above and its proposed constant from below before comparison. No floating-point arithmetic or tolerance is used.

The script also checks 19440 block-minimum identities exactly with rational powers of two, including 8505 zero-amplitude cases. All pass. These finite experiments do not establish the infinite series the-

orem; Lean proves that theorem for all allowed parameters. They do not verify the remaining rank construction, duality, full strong corollary or prime-square operator inputs.

The nine completely proved unconditional numbered paper results remain unchanged. Lemma 3.21 retains its earlier explicit PNT limits independently. The archived manuscript and accepted revision fragments are unchanged; no new manuscript correction has been established.

`Inverse_Fifth_Major_Arc_Error.md`

Explicit absorption into the inverse fifth power of R

Checkpoint 28. This unit proves the R^-5 major-arc error from the previous explicit error budget, under three displayed numerical conditions. The next unit establishes these conditions uniformly for the manuscript's choice of R. The raw progression estimate remains a hypothesis.

Assume N>=1, R>=1, C>=0 and an actual progression-prefix error bounded throughout [N/2,N] by

$$NC\exp(-c\sqrt{\log N}).$$

The same beta>0 and character data must be used over that interval. The major-arc range is q<=R^(11/10), abs(theta)<=R/(q*N^2).

Exponential absorption

For R>0, the condition 7*log(R)<=t implies

$$R^2e^{-t}=\exp(2\log R-t)\le\exp(-5\log R)=R^{-5}.$$

`exponential_majorArc_absorption` proves this for every real t. In the application t=c*sqrt(log N). There is no unspecified loss in its constant.

The nonunit contribution

Suppose additionally

$$\log R\le\log N,\qquad R^5\log N\le\sqrt{N}.$$

Since sqrt(N)<=N for N>=1, these hypotheses give R^5*log(R)<=N and R^5*sqrt(N)*log(N)<=N. Multiplying the nonunit budget by the positive R^5 and N therefore proves

$$\frac{2\log R+2\sqrt{N}\log N}{N}\le\frac{4}{R^5}.$$

The exact square-root identity, positivity of N, and every denominator cancellation are checked in `nonunit_majorArc_absorption`.

Bound for the actual symbol

Combining the two calculations with checkpoint 27 proves

$$\begin{aligned}&\left|\widehat{\widetilde{A}}_{N,\Lambda}(a/q+\theta)-(\mathfrak{s}(a,q)M_{N,1}(\theta)-\mathfrak{s}_\chi(a,q)\kappa M_{N,\beta}(\theta))\right|\\&\le\frac{4+(2+4\pi)C}{R^5},\end{aligned}$$

provided the three displayed conditions hold, including 7*log(R)<=c*sqrt(log N). This is `annularMangoldt_majorArc_inverse_fifth`. It is a theorem about the genuine annular Fourier sum, including all von Mangoldt prime powers. The constant depends only on the raw prefix-error constant C.

This proves the conditional inverse-fifth deduction with finite, checkable parameter hypotheses. It does not yet remove those numerical hypotheses for the source's N,Q range, prove existence of the analytic prefix estimate, or establish the independent minor-arc bound. Full Lemma 6.5, Proposition 4.19 and Theorem 1.1 remain open.

Module	New named theorems	Result
ExponentialMajorArcBudget.lean	4	Exponential absorption, nonunit absorption, combined error and the actual conditional inverse-fifth major-arc theorem

No new deep theorem is assumed in this unit, and no numerical experiment is used as a substitute for these Lean proofs.

<!-- checkpoint-verification -->

Verification

All 92 project modules and the root were freshly rebuilt: 3607 jobs pass without warnings/errors. All 749 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 94 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Low_Ramanujan_Bound.md`

Lemma 3.20: a complete checked logarithmic bound

Checkpoint 08, 22 October 2026. Source: `Draft5.tex`, label `l:lowramanujan`, near line 1885; typeset number 3.20. The archived full-source SHA256 remains `d2c31b96cb15b00feac09ed4fd9a2b0482726c719c4b772320c0711875d04660`.

The lemma is proved as stated, for every real Q>=3 and every integer n. The implied constant is absolute, independent of both variables. The manuscript proof cites Mertens' theorem. The formal proof supplies an elementary sufficient prime-product bound, so **Mertens' theorem is not an assumed input**. No change to the statement of this lemma is needed.

The statement and the actual sums

Keep the checked definition

$$C_q(n) = \sum_{u \in A_q} c_q(n-u^2), \qquad w_n(q) = \frac{|C_q(n)|}{q\phi(q)}.$$

The Ramanujan sums are the genuine sums of the standard complex additive character over units. `cohenWeight_eq` explicitly identifies the formal `cohenWeight` with this source expression at every positive q. The harmless natural-number extension has weight zero at q=0 and weight one at q=1.

The proved bound is

$$\sum_{P^+(q)<Q} w_n(q) \le C \log Q, \qquad C = 5e^2\left(12 + \frac{2}{\log 3}\right).$$

The constant is explicit and deliberately unoptimized. The theorem `low_ramanujan_uniform_bound` states the uniform quantifiers as an existence of one positive C valid simultaneously for all real Q>=3 and all integer n.

1. Establish finite support and the exact Euler product

The checked Cohen factorization gives C_q(n)=0 whenever an odd prime square divides q or 16 divides q. This is pointwise in every integer n, so the same vanishing holds for the nonnegative weight w_n(q).

CRT multiplicativity of C_q and multiplicativity of the totient imply w_n(mr)=w_n(m)w_n(r) for coprime m,r. Complex norm multiplicativity handles the absolute values. No sign restriction on C_q is assumed.

For an integer cutoff N>=3, every possible nonzero smooth coefficient divides M=((N-1)!)^3. Conversely every divisor of M has all prime factors below N. The formal infinite sum is therefore exactly its finite divisor sum over M. The previously checked divisor Euler identity has been generalized from complex values to any commutative semiring; this proof now also applies to real weights.

After the proved vanishing removes higher exponents, the exact product is

$$\sum_{P^+(q)<N} w_n(q) = (1 + w_n(2) + w_n(4) + w_n(8)) \prod_{2<p<N} (1 + w_n(p)).$$

This step uses proved finite support rather than an unproved interchange of an infinite series and a product.

2. Bound every local factor uniformly in n

The explicit Cohen factors at 2,4,8 have absolute values at most 1,4,16. Their denominators q*phi(q) are respectively 2,8,32. Hence

$$1 + w_n(2) + w_n(4) + w_n(8) \le \frac{5}{2}.$$

At an odd prime p the two Cohen values are p+1 and 1-p, so

$$w_n(p) \le \frac{p+1}{p(p-1)}.$$

Consequently the entire series is at most

$$\frac{5}{2} \prod_{2<p<N} \left(1 + \frac{p+1}{p(p-1)}\right).$$

The estimates include n=0, negative n, primes dividing n, and every residue case; no restriction on n enters the following prime-product argument.

3. An elementary logarithmically weighted prime sum

Let S be any finite set of primes p<=N. The first term of Legendre's formula for the factorial gives floor(N/p)<=v_p(N!). Multiplication by log(p)>=0 and summation therefore give

$$\sum_{p \in S} \left\lfloor \frac{N}{p} \right\rfloor \log p \le \log(N!).$$

The elementary bound N!<=N^N implies log(N!)<=N log(N). Also

$$\sum_{p \in S} \log p \le \log\left(\prod_{p \le N} p\right) \le N \log 4,$$

using the primorial bound already proved in pinned Mathlib. Since N/p<=floor(N/p)+1, the two estimates imply

$$\sum_{p\in S}\frac{\log p}{p}\le \log N+\log 4.$$

The actual factorial, prime factorization and primorial inequalities are used in Lean. This is not an assumed weighted-prime estimate.

4. The subset expansion and its first logarithmic moment

For t a subset of S put d(t)=product_(p in t) p, including d(empty)=1. Define

$$P(S)=\prod_{p\in S}\left(1+\frac{1}{p}\right)=\sum_{t\subseteq S}\frac{1}{d(t)}.$$

Distinct subsets have distinct products, by unique prime factorization. Expanding the finite product and its first logarithmic moment gives

$$\sum_{t\subseteq S}\frac{\log d(t)}{d(t)}=P(S)\sum_{p\in S}\frac{\log p}{p+1}.$$

`weighted_powerset_moment` proves the underlying product identity by induction on S. It imposes no probability-theoretic assumption. The logarithm of the product is then identified with the sum of the logarithms.

For N>=3, log4<=2 log(N). The preceding weighted-prime sum therefore yields

$$\sum_{t\subseteq S}\frac{\log d(t)}{d(t)}\le 3P(S)\log N.$$

5. Concentrate the mass below N^6

Let A be the reciprocal mass of subsets with d(t)<=N^6, and B the remaining mass. Then P=A+B. Every product in B has log d(t)>=6 log N, so the moment bound gives

$$6B\log N\le 3P\log N,\qquad B\le P/2.$$

The products counted in A are distinct positive integers at most N^6. Thus A<=H_(N^6), where H is the harmonic sum. The checked bound H_m<=1+log(m) gives

$$P\le 2A\le 2+12\log N\le\left(12+\frac{2}{\log 3}\right)\log N.$$

This proves the sufficient Mertens-type upper bound by finite sums and an elementary harmonic estimate. It does not assert Mertens' asymptotic formula.

6. Control the summable correction in the source product

For p>=2,

$$1+\frac{p+1}{p(p-1)}=1+\frac{1}{p}+\frac{2}{p(p-1)}\le\left(1+\frac{1}{p}\right)\left(1+\frac{2}{p(p-1)}\right).$$

The elementary telescoping identity

$$\sum_{j=0}^{m-1}\frac{1}{(j+1)(j+2)}=1-\frac{1}{m+1}$$

implies sum_(p in S) 1/(p(p-1))<=1. Applying 1+u<=exp(u) to the nonnegative correction factors shows their product is at most e^2. Hence

$$\prod_{p\in S}\left(1+\frac{p+1}{p(p-1)}\right)\le e^2\left(12+\frac{2}{\log 3}\right)\log N.$$

Combining with the factor 5/2 proves the integer-cutoff estimate with constant C/2. Every sum and product in this argument is finite.

7. Preserve the strict cutoff for all real Q>=3

Put N=ceil(Q). For an integer prime p, p<N is equivalent to p<Q, including exact prime endpoints. Thus the real-cutoff series is exactly the already bounded integer-cutoff series. Since Q>=3, N<=Q^2 and log N<=2 log Q. The additional factor two gives the stated constant C for all real Q>=3.

Verification and scope

All 21 modules were freshly compiled locally with pinned Lean 4.34.1 and Mathlib `d13f23b723b8a846827a245b89c10fc7d3f11612`. All 186 named project theorems pass the transitive axiom audit: only propext, Classical.choice and Quot.sound occur. The source scan passes for 23 Lean files. There are no proof placeholders, native proof shortcuts, or added mathematical axioms.

The exact rational experiment checks 4,640 cases, covering every residue class in the full period for each of twelve integer/noninteger cutoffs. The actual supported-modulus sum agrees with its Euler product and satisfies the rational local-factor majorant in every case. See `verification/low-ramanujan-numerical.json`. The logarithmic estimate is proved in Lean; these finite experiments supply supplementary evidence.

The user has confirmed applying both the Lemma 3.14 and Corollary 3.16 statement replacements. No further correction is requested for those supplied updates. The archived full source and PDF retain their original hashes. No headline theorem is yet complete and no deep analytic input has been assumed.

`Major_Arc_Error_Budget.md`

A uniform explicit major-arc error budget

Checkpoint 27. This unit reduces the proved error for the actual annular von Mangoldt symbol to a single R-dependent bound. It uses the raw progression-prefix hypothesis from checkpoint 26; no new distribution theorem or own-paper conclusion is assumed.

For N>=1, q>=1, R>=1 and delta>=0, suppose

$$q \le R^{11/10}, \qquad |\theta| \le \frac{R}{qN^2}, \qquad |C_{q,u}(t) - H_{q,\kappa\chi(u),\beta}(t)| \le N\delta \quad (N/2 \le t \le N)$$

for every reduced residue u. The actual C,H,chi and beta>0 are the objects defined in the previous unit. The same exceptional data are used throughout this interval; no consistency across different N is asserted.

The denominator and frequency calculation

The width condition implies q*abs(theta)*N^2<=R, by multiplying by the positive q*N^2. Since R>=1, real-power monotonicity gives R^(11/10)<=R^2, and also R<=R^2. Totient(q)<=q therefore implies

$$\phi(q)\delta(2 + 4\pi|\theta|N^2) \le \delta(2q + 4\pi R) \le (2 + 4\pi)R^2\delta.$$

This explicitly removes the dependence on q and theta from the residue error in the whole source major-arc range. Positivity conditions are displayed in Lean rather than used implicitly in denominator cancellation.

Monotonicity of the logarithm and log(R^2)=2*log(R) give log(q)<=2*log(R). Substitution into the previously proved nonunit bound produces the following result for the genuine finite Fourier symbol:

$$\begin{aligned}\left|\widetilde{A}_{N,\Lambda}(a/q+\theta) - (\mathfrak{s}(a,q)M_{N,1}(\theta) - \mathfrak{s}_\chi(a,q)\kappa M_{N,\beta}(\theta))\right| \\ \le \frac{2\log R + 2\sqrt{N}\log N}{N} + (2+4\pi)R^2\delta.\end{aligned}$$

`annularMangoldt_majorArc_source_R_budget` is the paper-facing theorem. An earlier theorem proves the same bound under the weaker denominator restriction q<=R^2. This is a quantitative implication, with an explicit constant, all prime powers retained and the exact annular normalization.

Scope and continuation

The next step absorbs these two positive errors into a constant times R^-5 and proves the required parameter inequalities for the source's R=max(exp((log N)^(1/10)),Q^8). The raw progression estimate

remains an explicit analytic input. The independent minor-arc statement and full Lemma 6.5 remain open. Theorem 1.1 is an explicit later target, after Proposition 4.19 and the application of the proved abstract high-low result.

Module	New named theorems	Result
MajorArcErrorBudget.lean	6	Positive-denominator phase budget, real-power and logarithmic bounds, totient error control and actual major-arc error reduction

There is no new numerical experiment or new deep assumption in this unit.

<!-- checkpoint-verification -->

Verification

All 91 project modules and the root were freshly rebuilt: 3606 jobs pass without warnings/errors. All 745 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 93 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Orlicz_A_Scalar_Balance.md`

Theorem 4.1: Orlicz growth and sharp A_N scalar balance

Checkpoint 14 continues the B_N endpoint proved in checkpoint 13. It proves four new modules, containing 34 named theorems, for the A_N proof. Theorem 4.1 remains partial: its uniform A_N conclusion from actual operator norm hypotheses has not yet been assembled.

Source and exact scope

The source is `sources/current/Draft5.tex`, Theorem 4.1, `t:improvinggeneral`, with `e:Abalance`, `e:endimprovan`, `e:cstar`, `e:Lognotation` and `e:defPhi`. The archived TeX/PDF are unchanged.

The new modules are:

Module	Checked content
`OrliczGrowth.lean`	Exact Phi identities, three limits, bounded-error control, uniform logarithmic absorption and uniform sub-power bounds
`OrliczBalance.lean`	Literal high-weight scaling, sharp leading coefficient, strict balancing margins, actual dyadic choice and all three exponent limits
`OrliczScalar.lean`	Exact normalization of low/high terms and a bound for the actual three-term scalar sum at that dyadic choice
`OrliczCutoff.lean`	Complementary density-range absorption, admissibility of the selected Q and the actual error decay factor

No endpoint estimate for A_N, scalar optimization theorem, analytic asymptotic or prime distribution theorem is assumed. Each limiting and inequality statement is proved from the pinned Mathlib. The functions q used in intermediate scaling lemmas are general real functions; the final scalar lemmas construct an actual dyadic Q. The final `exists_admissible_dyadic_orlicz_bound` does not take a desired asymptotic of Q as a hypothesis.

Exact logarithmic conventions

Write

$$L = \mathrm{Log}\,\delta = 2 + |\log \delta|, \qquad W_\kappa(L) = \frac{L^\kappa}{2 + \log L}.$$

The definition `orliczWeight` is exactly W. The checked identity is

$$\Phi_{c,\kappa}(\delta) = \exp(cW_\kappa(\operatorname{Log}\delta)).$$

For 0<delta<=1, L=2-log(delta), and delta=exp(2-L). The identity `paperLog_exp_two_sub` is proved for every L>=2. The additive twos in the paper's definitions are retained throughout.

For kappa>0 the module proves

$$\frac{\log L}{W_\kappa(L)} \to 0, \qquad \frac{1}{W_\kappa(L)} \to 0.$$

For kappa<1 it proves W_kappa(L)/L -> 0. For the first limit, the exact quotient is `(2 log L + (log L)^2)/L^kappa`. Both terms tend to zero by Mathlib's proved logarithm-versus-power limits. The inverse-weight limit uses `(2+log L)/L^kappa`. The sublinear-weight limit factors as `L^(kappa-1)/(2+log L)`.

These limits yield actual uniform estimates, including their bounded range:

- For every kappa>0, c>0 and real m, there is D>0 such that `(Log x)^m <= D*Phi(c,kappa,x)` for every x. In particular this holds for every positive density.
- For 0<=kappa<1, c>=0 and epsilon>0, there is D>0 such that `Phi(c,kappa,delta) <= D*delta^(-epsilon)` simultaneously for 0<delta<=1.
- Consequently `delta^theta*Phi(c,kappa,delta)` is bounded by `D*delta^(theta-epsilon)` on that same interval, for arbitrary real theta.

Constants are quantified before delta. The bounded-range argument selects a fixed threshold U>=2 and uses elementary real-power inequalities below U. Thus these are not only statements about an unspecified sufficiently small density. The last estimate is useful for the later interpolation argument; that corollary itself is still open.

Literal high denominator

The high term in `e:highgeneral` uses `(log Q)^kappa/log(log Q)`. Put q=log Q. For any function q(L) with q(L)/L -> k>0, the proof establishes

$$\frac{\log q(L)}{\log L} \to 1, \qquad \frac{q(L)^\kappa/\log q(L)}{W_\kappa(L)} \to k^\kappa.$$

The logarithmic ratio follows by taking the logarithm of q(L)/L, whose limit is log(k), and dividing by log L -> infinity. For the second ratio, the exact algebra is

$$\frac{q(L)^\kappa/\log q(L)}{L^\kappa/(2+\log L)} = \left(\frac{q(L)}{L}\right)^\kappa \frac{1+2/\log L}{\log q(L)/\log L}.$$

All needed positivity and nonvanishing conditions hold eventually and are checked in Lean. The literal denominator and the paper's LogLog denominator are connected by this proved limit, with no informal replacement of one by the other.

Sharp coefficient and actual dyadic scale

Let u=s+r, k=1/(2u), where s,r>0. Define

$$c_{\text{lead}} = \frac{c_1 s}{2^\kappa u^{\kappa+1}} = s\frac{c_1 k^\kappa}{u}.$$

`orliczLeadingCoefficient_eq` proves this equality with real powers. Given cstar>c_lead and c1>0, the proof chooses b satisfying

$$\frac{c_1 k^\kappa}{u} < b < \frac{cstar}{s}.$$

In particular b>0 and

$$sb < cstar, \qquad c_1 k^\kappa - rb < sb < cstar, \qquad -rb < cstar.$$

The candidate logarithm is y(L)=kL+bW_kappa(L). Since W/L -> 0, y/L -> k, so y -> infinity. An actual dyadic Q=2^n is chosen by rounding exp(y) down:

$$Q \le e^{y(L)} < 2Q.$$

For all L the chosen Q is at least two. The two-sided rounding bounds hold for sufficiently large L. They give `abs(log Q-y(L)) <= log 2`. The inverse-weight limit proves

$$\frac{\log Q - kL}{W_\kappa(L)} \to b.$$

The index function n(L) is fixed before the low logarithmic power alpha, the error power M, the error decay exponent A and N. Its existence is proved using the earlier dyadic rounding lemma; it is not an extra hypothesis.

The three actual scalar terms

Set delta=exp(2-L), q=log Q and theta=1-s/(2u). After division by delta^theta, the low, high and error terms are exponentials with respective exponents

$$\begin{aligned} E_{\text{low}} &= s(q-kL) + \alpha \log q + 2sk, \\ E_{\text{high}} &= -r(q-kL) + c_1 q^\kappa / \log q - 2rk, \\ E_{\text{err}} &= -r(q-kL) + M \log q - 2rk. \end{aligned}$$

The equalities for this normalization are proved in `orlicz_low_term_exact` and `orlicz_high_term_exact`; the constants from the additive two in L are included. The three exponent ratios tend to

$$E_{\text{low}}/W \to sb, \quad E_{\text{high}}/W \to c_1 k^\kappa - rb, \quad E_{\text{err}}/W \to -rb.$$

The polynomial logarithms vanish in these ratios by the proved limits. The strict margins therefore give, for all sufficiently large L,

$$\begin{aligned} \delta Q^s (\log Q)^\alpha + \delta^{1/2} Q^{-r} \exp\left(c_1 \frac{(\log Q)^\kappa}{\log\log Q}\right) + \delta^{1/2} Q^{-r} (\log Q)^M \\ \le 3\delta^\theta \Phi_{cstar,\kappa}(\delta). \end{aligned}$$

This is `exists_dyadic_orlicz_scalar_bound`. It is an inequality for the actual terms, beyond a limit calculation of their logarithms. The density threshold may depend on alpha and M, as allowed for fixed theorem parameters. The proof uses strict margins for the epsilon formulation of the conclusion. It does not need bounded-factor comparability of the low and high terms at the paper's first-order displayed choice.

Cutoff and error decay

The dyadic choice satisfies log Q<=y(L), while y(L)/L -> k. Consequently log Q <= (k+1)L eventually. If

$$L \le \frac{c_0}{k+1} (\log N)^c,$$

the source cutoff log Q <= c0*(log N)^c follows. This is checked for the same Q as in the scalar inequality.

For N>=1 and A>=0, `error_decay_factor_le_one` proves `(1+log N)^(-A) <= 1`. All other factors of the error term are nonnegative, so multiplying by this decay factor preserves the scalar upper bound. `exists_admissible_dyadic_orlicz_bound` combines the cutoff, the actual dyadic choice and the three-term bound with this decay factor. It works uniformly in N and A once the sufficiently-large-L condition holds. The source's separate constants implicit in the operator bounds and C_A must still be carried through the operator bridge; they are not certified as equal to one.

Complementary density range

For any d>0, a>=0, c>0 and x>=0, the elementary cutoff implication is proved:

$$dx^c \le L \quad \Longrightarrow \quad x^a \le d^{-a/c} L^{a/c}.$$

It follows that for any real theta,tau and cstar,kappa>0, one D>0 works for all N>=1 and 0<delta<=1 satisfying `d*(log N)^c <= Log delta`:

$$(\log N)^a \delta^\theta (\mathrm{Log}\,\delta)^\tau \le D\delta^\theta \Phi_{cstar,\kappa}(\delta).$$

This is `log_density_domination_le_orlicz`. Applied to the already proved B_N exponent tau, it is the scalar absorption required in the complementary range of the source proof. The positive-operator domination and finite pairing bridge needed for that application remain to be connected.

What remains before marking Theorem 4.1 complete

1. Deduce the actual three-piece A_N pairing inequality from its genuine l1-to-linfinity and l2-to-l2 operator hypotheses, retaining the fixed operator constants and the chosen C_A. Use the existing indicator/lp infrastructure from the B_N proof.
2. Connect positive B_N kernels and the stated A_N domination to a pairing domination; use the B_N theorem and the complementary-range scalar bound.
3. Handle the bounded-density range uniformly, including bounded N and an empty admissible Q range. A fixed Q=2 or 4 may only be used after proving it is admissible. State the discrete N domain explicitly; the new cutoff and error-decay results assume N>=1.
4. Include empty input/test sets and combine all ranges with one constant quantified before N,F,G. Only then mark `e:endimprovan` and the full theorem complete. The following interpolation corollary and the prime-square operator norm estimates are later obligations.

No new source correction has been established in this checkpoint. No unproved own-paper lemma has been classified as a deep external input. The existing explicit PNT hypotheses in Lemma 3.21 remain separate and are not used anywhere in these four modules.

Verification

The checkpoint contains 50 project modules and 406 named project theorems. All 50 modules receive a fresh local build with the artifact cache disabled; all 406 named theorem declarations receive the complete transitive axiom audit. The whitelist is exactly propext, Classical.choice and Quot.sound. The source scan covers 52 Lean files. See the accompanying current logs.

No new numerical experiment is claimed for these unbounded real-parameter analytic estimates. Their verification is the Lean proof. Earlier finite experiments are preserved with their original scopes, including the B_N rational scalar and Gaussian-integer convolution checks; those experiments do not validate the new A_N asymptotics. The ZIP manifest is checked against every archived entry, and the frozen paper sources keep their recorded hashes.

`Prefix_Error_Transport.md`

Quantitative transport of the actual progression-prefix error

Checkpoint 25. This unit turns a bound on the actual progression prefix into a bound on the quadratically weighted residue sum. It proves the integration-by-parts deduction; the progression distribution estimate itself remains an explicit input boundary.

Prefix-error integral

Let g(t)=exp(-2*pi*i*theta*t^2), as constructed previously. Suppose 0<=a<=b<=N and R is a complex function satisfying |R(t)|<=B on [a,b]. The exact derivative bound gives

$$\left| \int_{(a,b]} g'(t) R(t)\, dt \right| \le 4\pi |\theta| N B (b-a).$$

Both endpoint terms have norm at most B, because |g|=1. The triangle inequality therefore proves

$$|g(b)R(b) - g(a)R(a) - \int_{(a,b]} g'(t)R(t)\, dt| \le B(2 + 4\pi|\theta|N(b-a)) \le B(2 + 4\pi|\theta|N^2).$$

The last inequality uses b-a<=N and B>=0. The explicit 2 is the sum of two endpoint bounds. The integral estimate uses Mathlib's actual Bochner integral norm bound. No differentiability assumption on the prefix-error function is needed.

Subtracting a differentiable model

Let C(t) be the actual complex progression von Mangoldt prefix from `progressionMangoldtPrefix`. Let H,H' be complex functions such that H has derivative H' at every point of [a,b], and H' is interval-integrable. All these regularity conditions will be discharged for the source model in the next unit.

We first prove integrability of g'(t)C(t), using Mathlib's theorem for a smooth factor times a floor-indexed finite prefix. Continuity of H and integrability of g' give integrability of g'H. Thus subtracting their integrals is justified, rather than used as a formal rule without its hypotheses.

Integration by parts for gH gives

$$\int_{(a,b]} g(t)H'(t)\,dt = g(b)H(b) - g(a)H(a) - \int_{(a,b]} g'(t)H(t)\,dt.$$

Subtract this from the actual Abel identity proved in checkpoint 24:

$$W_r - \int_{(a,b]} g(t)H'(t)\,dt = g(b)(C(b)-H(b)) - g(a)(C(a)-H(a)) - \int_{(a,b]} g'(t)(C(t)-H(t))\,dt.$$

`squareResidueSum_model_error_identity` proves this exact identity. W_r is the actual unnormalized residue sum with the floor cutoffs at a,b. It includes all von Mangoldt prime powers and the paper's negative phase.

Applying the prefix-error bound with R=C-H proves

$$|W_r - \int gH'| \le B(2+4\pi|\theta|N^2).$$

The hypothesis is a bound on the genuine unweighted prefix C-H; no weighted-residue estimate or own-paper lemma is assumed.

Annular normalization

Take a=N/2, b=N with N>=1. If the actual prefix difference is bounded by N*delta throughout [N/2,N], then the normalized residue error is

$$\left|\frac{W_r}{N} - \frac{1}{N}\int_{N/2}^{N} g(t)H'(t)\,dt\right| \le \delta(2+4\pi|\theta|N^2).$$

`annularProgressionModel_error_bound` proves this statement. The real lower endpoint and natural floor cutoff are matched explicitly. Positivity of N justifies cancellation of 1/N against the prefix error N*delta. No additional N factor is lost. Delta>=0 is displayed.

Files

Module	New named theorems	Result
PrefixErrorBounds.lean	2	Endpoint plus derivative error bounds, including the N^2 version
ProgressionModelError.lean	4	Actual prefix-product integrability, exact model subtraction, quantitative and normalized annular bounds

The next unit proves regularity and the derivative of the source model x/phi(q)-z*x^beta/(beta*phi(q)), for beta>0 on a positive interval, and identifies its integral with the actual ordinary and exceptional oscillatory integrals. The raw progression-prefix estimate remains an explicit analytic boundary. The final R^-5 and minor-arc statements of Lemma 6.5 are not concluded here.

<!-- checkpoint-verification -->

Verification

All 88 project modules and the root were freshly rebuilt: 3603 jobs pass without warnings/errors. All 723 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 90 Lean files. Exact unique import/audit coverage and unchanged

frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Prime_Square_Operators.md`

Actual prime-square operators and annular reconstruction

Checkpoint 21 constructs the source's actual von Mangoldt and ordinary square averages, proves their elementary operator inputs, and proves the exact annular identities and dyadic reconstruction. Five modules add 48 named theorems. All 75 modules and the root have a fresh clean build (3482 jobs); all 613 named theorems pass the transitive axiom audit, and 77 Lean files pass the source scan.

Proposition 4.19 is still open. Its Fourier low, high, error and maximal estimates are not proved or assumed in these new results. No headline prime-square application is counted as complete. The abstract Theorem 4.1 and full abstract Corollary 4.15 remain complete.

Source definitions and domains

The source averages are equation `e:basicaverages`, near line 993 of `sources/current/Draft5.tex`:

$$A_{N,w}f(x) = \frac{1}{N}\sum_{0<n\le N} w(n)f(x-n^2).$$

The two weights are w(n)=1 and Mathlib's actual ArithmeticFunction.vonMangoldt. In particular, Lambda(p^j)=log(p) for every j>=1. Prime powers are retained. Replacing Lambda by a sum over primes alone would change the source operator.

N is the arithmetic cutoff; the spatial scale is N^2. The formal definitions take N:Nat, which includes all dyadic scales in Proposition 4.19. The elementary uniform norm theorems apply to every N>0. The definitions also have a total N=0 extension, giving zero operators; the source's positive-scale statements do not rely on that extension.

For every finite sequence-space exponent P with 1<=P and p=P.toReal>0, weightedSquareAverage hp N w is a genuine continuous complex-linear map lp(P)->lp(P). Its underlying coordinate expression is precisely the displayed sum. The annular definition is

$$\widetilde{A}_{N,w}f(x) = \frac{1}{N}\sum_{N/2<n\le N} w(n)f(x-n^2),$$

using natural integer division for N/2. This is the source's `e:tildedef2` at dyadic scales. No finite-support restriction on f is imposed on either continuous operator.

Constructing the actual operators and kernels

integerTranslate hp d sends f(x) to f(x-d). Its membership in lp follows by reindexing the summable norm powers through the integer translation bijection. Reindexing the norm sum proves exact norm preservation. The map is complex-linear and continuous with operator norm at most one.

For a finite S:Finset Nat and a real normalizer c, define

$$T_{S,c,w} = c\sum_{n\in S} w(n)\tau_{n^2}, \qquad K_{S,c,w}(z) = c\sum_{n\in S}\mathbf{1}_{z=n^2}w(n).$$

finiteSquareOperator and finiteSquareKernel are these actual objects, with real coefficients embedded in the complex scalars. The norm bound

$$\|T_{S,c,w}\| \le |c|\sum_{n\in S}|w(n)|$$

follows from the triangle inequality and the translation norm bound. For c>=0 and nonnegative weights this is at most c*sum w(n).

The proof natSquare_int_injective checks injectivity of n->n^2 from nonnegative natural indices into the integers. Consequently the kernel at m^2 is c*w(m) when m belongs to S and is zero otherwise. It is zero outside the finite image of S. Positive coefficients give a nonnegative real-valued kernel, and coefficientwise domination gives kernel domination.

finiteSquareKernel_finiteInput proves the exact identity with the existing finiteConvolution for every finite set and arbitrary complex coefficients. It interchanges the two finite sums and uses x-y=n^2 iff y=x-n^2. Thus the continuous maps agree with actual convolution; they are not unrelated maps with only a scalar norm model.

Module	New named theorems	Checked role
FiniteSquareOperators.lean	8	Genuine lp translations, coordinates and finite operator norm
SquareAverageKernels.lean	12	Actual kernel, finite convolution, positivity, support and local bound
WeightedSquareAverages.lean	10	Full/annular definitions, normalization, mass and spatial scale
PrimeSquareAverages.lean	10	Actual Lambda, elementary Chebyshev bound and source elementary inputs
DyadicSquareReconstruction.lean	8	Exact half subtraction, telescoping, reindexing and both bottom terms

Uniform norms without a PNT assumption

Mathlib's pinned Chebyshev theorem psi_le_const_mul_self proves

$$\sum_{0<n\le N}\Lambda(n)=\psi(N)\le(\log 4+4)N.$$

The equality of the sums, including their endpoint conventions, is checked in mangoldt_square_mass_bound. It uses the natural-floor identity at N. This is an elementary upper bound already proved in Mathlib, not an unformalized PNT input. Put C_Lambda=log4+4>0.

The actual full and annular operator norms are at most C_Lambda for Lambda and at most one for ordinary squares, uniformly over N>0 and every finite p>=1. The annular mass is bounded by the full mass because its index set is a subset and the weights are nonnegative. Normalizing by 1/N gives the bounds. In particular, the actual kernels satisfy the existing genuine KernelL2Bound definition with constants C_Lambda and 1.

These are bounds on each operator, uniform in N. They do **not** assert an l2 bound for the supremum over N. Proposition 4.19's maximal high estimate remains a separate open theorem.

Positivity, domination and the local spatial bound

For S contained in (0,N], the kernel vanishes outside [1,N^2] in the integers. The support theorem proves this from the actual square indices; it is not a support assumption.

Use the finite window W_N(x)=[x-N^2,x] intersected with the integers. The kernel support gives the exact localization

$$(K*\mathbf{1}_F)(x)=(K*\mathbf{1}_{F\cap W_N(x)})(x).$$

Injectivity of the square indices and the ordinary coefficient 1/N then give

$$|\widetilde{A}_{N,\mathbb{N}^2}\mathbf{1}_F(x)|\le N^{-1}\|\mathbf{1}_{F\cap W_N(x)}\|_1=(N^2)^{-1/2}\|\mathbf{1}_{F\cap W_N(x)}\|_1.$$

The equality of scale factors is proved in square_inverse_spatial_scale. The one-sided window is smaller than the source's symmetric window; the estimate supplies the indicator-local bound used by HighLowEndpointInputs.

Mathlib proves 0<=Lambda(n)<=log(n). Since 0<n<=N, logarithm monotonicity gives Lambda(n)<=log(N). Both actual kernels are positive, so summing coefficientwise domination proves

$$|\widetilde{A}_{N,\Lambda}\mathbf{1}_F(x)|\le\log N\,\widetilde{A}_{N,\mathbb{N}^2}\mathbf{1}_F(x)\le\log(N^2)\,\widetilde{A}_{N,\mathbb{N}^2}\mathbf{1}_F(x).$$

The last comparison is used at spatial scale N^2 with source a=1. These are the indicator versions consumed by the already checked abstract theorem. The structure AnnularSquareElementaryInputs packages both positive kernels, domination, localization bound and two genuine l2 bounds. annular_square_elementary_inputs constructs it for every N>0; none of its fields is an unproved assumption.

Exact annular difference and dyadic reconstruction

For every natural M and arbitrary real weight w, the actual continuous maps obey

$$\widetilde{A}_{2M,w} = A_{2M,w} - \tfrac{1}{2}A_{M,w}.$$

The proof splits (0,2M] into (0,M] and (M,2M], then checks the normalizers (1/2)*(1/M)=1/(2M), including M=0 in the total extension. There is no unjustified replacement of floor(N/2) by N/2 for odd N.

The base scale is A_(1,w)=w(1)*tau_1. Induction proves the weighted telescoping identity for N=2^k. Normalizing and reflecting the finite index range gives the source's descending order:

$$A_{2^k,w} = \frac{w(1)}{2^k}\tau_1 + \sum_{j=0}^{k-1} 2^{-j}\widetilde{A}_{2^{k-j},w}.$$

The sum is empty at k=0. The complex scalar coefficients are exactly the real dyadic coefficients embedded in C. The reflection and coefficient cancellation are checked, using nonvanishing of powers of two.

For Lambda, Mathlib proves Lambda(1)=0, so the bottom term vanishes. For ordinary squares, w(1)=1, so it is N^-1*f(x-1). The final declarations mangoldtSquareAverage_dyadic_reconstruction and ordinarySquareAverage_dyadic_reconstruction match the source formulas `e:annularreconstruction` and the following square-average identity. These are equalities of actual continuous maps, not only identities for indicators or finite coefficient arrays.

Remaining Proposition 4.19 dependencies

The source correspondence below distinguishes completed prerequisites from unproved conclusions. No listed open own-paper lemma is treated as a deep published theorem or assumed in the new Lean results.

Source	Dependency and remaining work
e:basicaverages, e:tildedef2, e:annularaverages, e:annularreconstruction	Actual definitions and operator identities now checked
Elementary hypotheses in the proof of Theorem 1.1	Positivity, indicator domination/localization and genuine uniform l2 bounds now checked at N^2
Lemma 6.5, l:prime-square-input	Open: exact annular Fourier sums, non-unit/prime-power bookkeeping, residue grouping and partial summation; published Landau--Page and minor-arc inputs need precise boundaries before use
Lemma 6.9, l:aaplemma	Open: actual major-arc model, separation, complementary range, approximation error and its Fourier-to-l2 bridge
Proposition 6.14, p:lowcontribution	Open: actual smooth low multiplier, inverse-transform decay, ordinary/exceptional arithmetic assembly and local maximal average
Lemma 6.16, l:notBourgain, and c:orlicz-prefix	Open: own-paper multifrequency and prefix estimates; no blanket transference or maximal assumption introduced
Proposition 6.21, p:highupperbound	Open: high and maximal high estimates, actual Gauss/conductor bounds, and exceptional characters varying with scale
Proposition 4.19, p:decompositionofan	Open: construct and join the low/high/error operators and every stated bound; elementary averages alone do not prove it
Theorem 1.1, t:improvingfixed	Open: apply the checked abstract theorems after the actual decompositions, then connect the annular endpoint and the general cutoff

The existing arithmetic results remain available. Lemma 3.21's sharp asymptotic still has its two earlier explicit PNT-limit hypotheses; any future consumption must retain that boundary. It is not used in this checkpoint's Chebyshev norm proof.

The next coherent unit is the genuine integer Fourier/Plancherel bridge and the exact finite multiplier identities. The pinned Mathlib source Mathlib.Analysis.Fourier.AddCircle already contains a Fourier Hilbert basis and Parseval infrastructure, but it has not yet been imported or connected here. Its basis

uses the positive phase, while the paper's transform uses e(-n*theta); the index/sign must be explicitly matched.

For later maximal bounds, q0, beta and the exceptional character are scale-dependent in Lemma 6.5. They must not be silently frozen across N. The low term's exceptional cutoff d<=Q/B0 and the complementary high terms must retain both the conductor and current-scale restrictions. The actual low and high kernels need not have the compact support of the original averaging kernel.

Verification and independent exact experiments

All 75 project modules and the root were freshly compiled with the artifact cache disabled: 3482 jobs pass without warnings or errors. Every one of the 613 named project theorems passes the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 77 Lean files with no placeholders or added mathematical axioms. Exact import/module and unique theorem/audit coverage were checked, as were all frozen source hashes. No Lean source changed after these checks.

scripts/check_square_averages.py uses rational coefficients of formal log(prime) symbols and exact Gaussian rational arithmetic; no floating point is used. It checks 1542 support cases, 1028 positivity cases, 387 annular difference identities, 39 ascending and 39 descending dyadic reconstructions through arithmetic cutoff 4096, 11256 complex finite convolution identities, 14280 local indicator bounds and 184 translation norm cases at exponents two and four. All pass.

Three diagnostics detect changed conventions: omitting prime powers loses log(2)/4 at shift 16 for N=4; omitting the ordinary-square bottom term loses 1/4 at shift one for N=4; using the half subtraction at odd N=3 incorrectly leaves -1/6 at shift one. The last diagnostic is outside the source's dyadic hypothesis and is not a manuscript error.

The experiment checks finite identities and elementary probes, not Chebyshev's analytic inequality, the full operator norm, a Fourier estimate or Proposition 4.19. Those current general elementary norm statements are Lean proofs. Exact ranges, digests and limitations are in verification/square-averages-numerical.json. The source manuscript and accepted revisions are unchanged; no new source edit is pending.

`Principal_Gauss_Bounds.md`

Lemma 3.21: the finite Gauss-sum argument

Historical checkpoint 09 exposition. Checkpoint 10 completes the remaining paper-specific asymptotic deduction with explicit PNT hypotheses; read `Sharp_Gauss_Asymptotic.md` for the current complete conditional statement.

Checkpoint 09, 22 October 2026. Source: `Draft5.tex`, label `l:inftyboundsaq`, especially `e:primepowerestimate` and `e:sproductbound`. The archived source SHA256 remains `d2c31b96cb15b00feac09ed4fd9a2b0482726c719c4b772320c0711875d04660`.

The finite arithmetic part is complete. The full sharp asymptotic statement of Lemma 3.21 is not yet complete. All prime estimates, prime-power vanishings, CRT coefficients, global support and the actual finite product bound below are proved in Lean. The remaining prime-distribution/asymptotic step is identified at the end. No new mathematical axiom or deep analytic input has been assumed.

Exact proved statement

For every positive integer q and every integer a coprime to q,

$$|\mathfrak{s}(a,q)| \le \frac{4}{\sqrt{q}} \prod_{\substack{p\mid q\\ p>2}} (1-p^{-1/2})^{-1}.$$

The sum vanishes if 16 divides q or an odd prime square divides q. More explicitly, a nonzero sum implies

$$q = 2^j d, \quad 0 \le j \le 3, \quad d \ge 1, \quad 2 \nmid d, \quad d \text{ squarefree}.$$

These are unbounded results for the actual exponential sums, not numerical observations or hypotheses about a proposed local model. The constant four is explicit and unoptimized. Modulus one is included; modulus zero is excluded by the positive-modulus convention.

1. Retain the actual definitions

Write

$$U_q(a) = \sum_{u \in A_q} e(au^2/q), \qquad G_q(a) = \sum_{r \bmod q} e(ar^2/q).$$

`unitQuadraticGaussSum` was already defined in the Cohen development. The new `completeQuadraticGaussSum` is exactly the second sum. The source's principal normalized square sum is

$$\mathfrak{s}(a,q) = \phi(q)^{-1} U_q(-a).$$

`principalSquareSum_as_unitGauss` checks this sign and normalization explicitly. The norm formula divides |U_q(-a)| by the real positive totient phi(q). All character values have norm one, so the triangle inequality and the actual unit-group cardinality give |s(a,q)|<=1, even without a being a unit.

2. Evaluate the complete sum at an odd prime

Let p be odd prime and a nonzero modulo p. Multiplying the complete sum by its complex conjugate and combining the characters gives

$$G_p(a)\overline{G_p(a)} = \sum_{u,v \bmod p} e(a(u^2 - v^2)/p).$$

The change of variables s=u-v, t=u+v is a bijection since two is invertible modulo p. Its inverse is u=(s+t)/2, v=(t-s)/2. The formal equivalence proves both inverse identities. Consequently the double sum is

$$\sum_{s,t \bmod p} e(ast/p) = p.$$

For s=0, every term in the inner sum is one. For s nonzero, additive-character orthogonality makes that inner sum zero. Taking the real norm square proves |G_p(a)|=sqrt(p).

The nonunits modulo a prime consist exactly of zero, whose quadratic phase is one. Thus U_p(a)=G_p(a)-1 and

$$|U_p(a)| \le \sqrt{p} + 1, \qquad |\mathfrak{s}(a,p)| \le \frac{\sqrt{p}+1}{p-1} = \frac{1}{\sqrt{p}-1}.$$

This proof uses a finite bijection and the already checked standard character orthogonality. No Gauss-sum evaluation theorem is assumed as a new input.

3. Reuse the checked cancellation at prime powers

The earlier Cohen work constructed a permutation of the units

$$u \longmapsto u + t/u$$

when t^2=0. It changes u^2 by 2t. If 2t is nonzero and a is a unit, the quadratic sum is multiplied by a character value different from one and therefore vanishes.

For q=p^j with p odd and j>=2, take t=p^(j-1). For q=2^j with j>=4, take t=2^(j-2). The required square-zero and nonzero-phase conditions are proved from exact divisibility inequalities. The new local theorems apply the previous generic cancellation directly to U_q(a), then to s(a,q).

This establishes the local support without relying on an unproved recurrence for the complete Gauss sum. At the three remaining powers of two the simple bound |s|<=1 gives sqrt(2^j)*|s|<=sqrt(8)<=4.

4. CRT with the correct coefficients

For coprime positive m,n, define the local coefficients

$$a_m = (a \bmod m)n^{-1} \pmod m, \qquad a_n = (a \bmod n)m^{-1} \pmod n.$$

The exact standard-character identity has these inverse-modulus factors. Reindexing the unit sum by the checked CRT equivalence proves

$$U_{mn}(a) = U_m(a_m)U_n(a_n), \qquad \mathfrak{s}(a, mn) = \mathfrak{s}(a_m, m)\mathfrak{s}(a_n, n).$$

The coefficient transforms are retained in the formal statements. This is the CRT factorization needed in the source's multiplicativity argument. Reduction preserves units, and each inverse-modulus factor is a unit, so unit a produces unit a_m,a_n. The local norm bounds are uniform in these coefficients. Multiplicativity of the totient and sqrt(mn)=sqrt(m)*sqrt(n) give the corresponding identity for sqrt(q)*|s(a,q)|.

5. Assemble a proved global majorant

For a prime power p^j define a real local majorant L(p,j). Its value at j=0 is one. For j>0 it is

$$L(p,j) = \begin{cases} 4, & p = 2,\ 1 \le j \le 3, \\ 0, & p = 2,\ j \ge 4, \\ (1 - p^{-1/2})^{-1}, & p > 2,\ j = 1, \\ 0, & p > 2,\ j \ge 2. \end{cases}$$

Each local majorant is proved to bound the actual scaled norm at that prime power. Define E(q) as the product of these local majorants over the canonical prime-power factorization of q. Disjoint prime supports prove multiplicativity of E on coprime inputs.

Induction on positive prime powers and coprime products, uniform in every unit coefficient, then proves

$$\sqrt{q}\,|\mathfrak{s}(a,q)| \le E(q).$$

Zero local factors force the global actual sum to vanish, since sqrt(q)>0. This proves the global support criterion. Extracting the full power of two from q and checking the remaining factorization gives the explicit odd squarefree decomposition above, including the case d=1.

The product E has at most one factor at two, bounded by four. Every other factor is bounded by (1-p^(-1/2))^(-1). Dividing the resulting inequality by sqrt(q) proves the stated finite product bound for every positive q and every unit coefficient. The integer wrapper uses the checked equivalence between a unit integer residue modulo q and coprimality of a,q.

6. The remaining analytic step: precise proposed route

This subsection is a continuation specification, **not a completed Lean proof and not an assumed input of the current project**. The full source lemma requires the asymptotic coefficient 2+o(1) and its sufficiently-large-q consequence with coefficient three.

Let L=log(q), let S be the prime divisors of q, and suppose L>=3. The squarefree prime product divides q, so sum_(p in S) log(p)<=L. Put

$$\theta(y) = \sum_{p \le y} \log p, \qquad W(y) = \sum_{p \le y} p^{-1/2}.$$

A useful finite threshold inequality is

$$\sum_{p\in S} p^{-1/2} \le W(y) + \frac{L-\theta(y)}{\sqrt{y}\log y}, \qquad y > 2.$$

To prove it, subtract log(p)/(sqrt(y)*log(y)) from each term. The difference is nonnegative below y and nonpositive above y, because sqrt(p)*log(p) is increasing for p>=2. Extend the nonnegative portion to all primes below y and use the logarithmic budget for S. This avoids needing an exact discrete maximizer for the source's smallest-primes argument.

The standard PNT consequences theta(y)=y+o(y) and W(y)=(2+o(1))*sqrt(y)/log(y), applied with y=L, give the leading bound needed for the sum over S. Any use of these results must expose their exact quantified statements and published source; the user has authorized leaving deep published theorems unformalized. No own-paper obligation should be silently replaced by an axiom.

The remaining correction admits an elementary bound:

$$\sum_{p\in S} \frac{1}{p} \le 1 + \log L + \frac{1}{\log 2}.$$

Below L, compare with the harmonic sum; above L, use the logarithmic budget to bound the number of primes. Also

$$\log(1-p^{-1/2})^{-1} \le p^{-1/2} + 4/p \quad (p \ge 2).$$

This follows from log(x)<=x-1 and (1-p^(-1/2))^(-1)<=4. The correction O(log L) and the fixed log(4) are o(sqrt(L)/log(L)). Formalizing these steps, the threshold argument, and the PNT input boundary is the next target. Only after those are connected should the full Lemma 3.21 be marked complete.

Verification and evidence

All 24 modules were freshly compiled with pinned Lean 4.34.1 and Mathlib `d13f23b723b8a846827a245b89c10fc7d3f11612`. All 227 named project theorems pass the transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan passes for 26 Lean files. No proof placeholders, native_decide, unsafe declarations or added mathematical axioms occur.

The independent script `check_principal_gauss.py` evaluates the actual Gauss sums as integer polynomials modulo the cyclotomic polynomial Phi_q. These are exact values at the primitive q-th root of unity; no floating point arithmetic is used. For q=1,...,128 and every unit a, it checks:

- 5,022 unit coefficients in total;
- 1,688 complete odd-prime norm-square identities;
- 1,689 prime zero-term removal identities;
- 1,088 bad-modulus vanishings;
- 8,630 exact CRT comparisons, including transformed coefficients and totients;
- the modulus-one value.

These categories overlap and are not a count of distinct paper statements. The data are in `verification/principal-gauss-numerical.json`. They are finite supplementary checks, not inputs to Lean and not evidence for the uncompleted sharp asymptotic. The earlier six completed paper results remain complete; no headline theorem is yet formally verified.

`Progression_Cohen.md`

Progression Cohen identities: checked proof specification

Checkpoint 05, 22 October 2026. Authoritative source: `sources/current/Draft5.tex`, SHA256 `d2c31b96cb15b00feac09ed4fd9a2b0482726c719c4b772320c0711875d04660`. The targets are Lemmas **3.11** (`l:progressioncohen`) and **3.12** (`l:sumoverramanujan`). Both are proved, including the latter's vanishing and prime-power factorization clauses. This document explains the actual checked proofs; it does not certify other statements in the paper.

Statements and source correspondence

Write A_q = (Z/qZ)^×, ψ_q(t)=exp(2πit/q), and

$$c_q(n) = \sum_{a \in A_q} \psi_q(na), \qquad C_q(n) = \sum_{u \in A_q} c_q(n - u^2).$$

These are the existing genuine complex exponential definitions in `QuadraticCohen.lean`. Complete-residue filters and unit-group sums were already proved equivalent. There is no replacement of these functions by an assumed closed formula.

All moduli q are positive. The progression modulus g divides q, so g and h=q/g are positive as well. Lemma 3.12 uses positive y. Inputs b,x,n can be arbitrary integers, including negative ones.

The congruence r≡b mod g is expressed by the canonical ring homomorphism ρ_g:ZMod q→ZMod g. In Lean, its divisibility proof is an argument of `ZMod.castHom`. The paper's gcd(b,g)=1 becomes `IsUnit (b : ZMod g)` or `IsCoprime (g : ℤ) b`; Mathlib's `ZMod.coe_int_isUnit_iff_isCoprime` supplies the formal equivalence. Using an actual unit b in the CRT proof adds no mathematical restriction.

Define

$$R_{q,g}(b, n) = \sum_{\substack{r \in A_q \\ \rho_g(r) = b}} c_q(n - r).$$

Lemma 3.11 is

$$R_{q,g}(b, n) = \begin{cases} \mu(h) c_h(n) c_g(n - b), & \gcd(g, h) = 1, \\ 0, & \gcd(g, h) > 1. \end{cases}$$

The product-modulus theorem takes q=gh with arbitrary positive g,h; this covers every positive q and divisor g. The divisor/quotient wrappers state the same result in the paper's notation. Their `NeZero (q/g)` instance only expresses the positivity already implied by g|q and q>0. The gcd and quotient instances used for Lemma 3.12 are constructed explicitly in its module.

Source component	Checked declarations
Ordinary Cohen identity used in the proof	`linear_cohen_identity`
Genuine Ramanujan sum at a unit equals μ(q)	`ramanujanAtOne_eq_moebius`, `ramanujanSum_unit_eq_moebius`
Lemma 3.11, product modulus	`progression_cohen_identity_mul`
Lemma 3.11, divisor notation and integer input	`progression_cohen_identity`, `progression_cohen_identity_int`
Lemma 3.11, arbitrary modular input	`progression_cohen_identity_residue`
Definitions e:mathfraks and e:upsilondef	`principalSquareSum`, `upsilon`
Opening the actual normalized sums	`normalized_upsilon_correlation_expansion`
Lemma 3.12, equation e:eqjustforLHS	`sum_upsilon_square_identity`
Its squarefree vanishing clause	`sum_upsilon_square_eq_zero_of_not_squarefree`
Its prime-power factorization clause	`sum_upsilon_square_prime_factorization`

All declarations are in namespace `PrimeSquares`. The general character-twisted sum s_χ from e:mathfraksgeneral is not defined or formalized in this checkpoint. Only the principal-character sum needed for these two lemmas is used.

1. Translation of the unit group

The proofs use an elementary fact valid in every commutative ring. If t²=0 and u is a unit, then u+t is a unit with inverse

$$u^{-1} - tu^{-2}.$$

Multiplication verifies this formula using t²=0 and uu⁻¹=1. Translation by −t is the inverse permutation. Lean constructs the units and both inverse identities explicitly in `nilpotentAddUnit` and `nilpotentAddEquiv`.

This is an additive translation of units. The earlier quadratic identity used the different permutation u↦u+t/u. Both are proved from ring identities; neither presupposes root lifting or any analytic theorem.

2. The ordinary linear Cohen identity

First prove c_q(1)=μ(q). At a prime p the existing exact evaluation gives c_p(1)=−1. At p^(k+2), take t=p^(k+1). Then t²=0 in the residue ring, but t≠0. Reindexing the unit sum by u↦u+t gives

$$c_{p^{k+2}}(1) = \psi_{p^{k+2}}(t) c_{p^{k+2}}(1).$$

The standard character is injective, so ψ(t)≠1. Therefore the sum is zero. CRT multiplicativity, together with the proved prime-power evaluations of the Möbius function, identifies c_q(1) with μ(q) at every positive modulus. The auxiliary function `ramanujanAtOne` extends this actual sum by zero at q=0 solely for a natural-number induction interface. Its agreement with c_q(1) at every positive q is proved.

Multiplication by any unit permutes the unit group, so c_q(a)=μ(q) for unit a. Now open the two finite sums:

$$\begin{aligned}\sum_{r \in A_q} c_q(n-r) &= \sum_{a \in A_q} \psi_q(na) \sum_{r \in A_q} \psi_q(-ar) \\ &= \sum_{a \in A_q} \psi_q(na) c_q(-a) = \mu(q) c_q(n).\end{aligned}$$

The coefficient −a is again a unit, including for even q. The Lean proof checks the reordering and phase signs before extracting the common factor. Modulus one is handled explicitly: it has one unit, its character is identically one, and μ(1)=1.

3. Lemma 3.11: the coprime case

Suppose gcd(g,h)=1 and q=gh. The existing checked CRT equivalence identifies A_q with A_g×A_h. The progression condition fixes the first coordinate to b; the second coordinate ranges over all units modulo h. The previously proved Ramanujan multiplicativity then gives

$$R_{q,g}(b,n) = c_g(n-b) \sum_{v \in A_h} c_h(n-v) = \mu(h) c_h(n) c_g(n-b).$$

Lean transports the unit sum by `crtUnitsEquiv`, proves that the canonical reductions are the two coordinates, evaluates the fixed-coordinate filter, and applies the ordinary Cohen identity. There is no assumption that the unscaled standard additive character factors under CRT: the earlier character scaling proofs establish Ramanujan multiplicativity with the correct phases.

4. Lemma 3.11: the shared-prime case

Suppose gcd(g,h)>1. Choose a prime p dividing both, and write g=pℓ, h=pk. Set t=gk=q/p. Then

$$t^2 = q\ell k, \qquad g \mid t, \qquad 0 < t < q.$$

Consequently t²=0 in ZMod q, ρ_g(t)=0, and t≠0. Translation by t therefore permutes precisely the units in the chosen progression class.

For a fixed unit coefficient a in the opened Ramanujan sum, reindexing this progression-restricted sum multiplies it by ψ_q(−ta). The phase is not one: injectivity of the character would give ta=0, and a is invertible, forcing t=0. Thus every such coefficient sum is zero, and so is R_(q,g)(b,n).

`progressionRamanujanSum_eq_zero_of_square_zero` proves the general translation argument. `progressionRamanujanSum_non_coprime` constructs t with all the required properties from the shared prime. This branch in fact holds for any b; coprimality of b is needed only for the nonzero coprime branch.

The argument covers all overlaps, not merely prime-power q. Degenerate cases g=1, g=q and q=1 enter the coprime branch and require no omitted exception.

5. Lemma 3.12: expansion and normalization

Use exactly the definitions in the paper:

$$\mathfrak{s}(a,q) = \frac{1}{\phi(q)} \sum_{u \in A_q} \psi_q(-au^2), \quad \Upsilon(a,q,b,y) = \frac{\phi(y)}{\phi([y,q])} \sum_{\substack{r \in A_q \\ r \equiv b \pmod g}} \psi_q(-ar), \quad g = \gcd(q,y).$$

All three totients φ(q), φ(y), φ([y,q]) are strictly positive. The formal proof establishes their nonvanishing in ℂ before cancelling the factors. The product of the three phases is

$$\psi_q(-ar)\psi_q(-au^2)\psi_q(ax) = \psi_q(a(x-u^2-r)).$$

Summing first over a gives the genuine Ramanujan sum, hence

$$\frac{\phi(q)\phi([y,q])}{\phi(y)}\sum_{a\in A_q}\Upsilon(a,q,b,y)\mathfrak{s}(a,q)\psi_q(ax)=\sum_{u\in A_q}R_{q,g}(b,x-u^2).$$

Applying the residue-input form of Lemma 3.11 term by term gives exactly

$$\mu(h)\mathbf{1}_{\gcd(g,h)=1}\sum_{u\in A_q}c_h(x-u^2)c_g(x-b-u^2),\qquad h=q/g.$$

The two reductions are explicit ring homomorphisms in Lean. In particular, the shift in the second factor is x−b−u², with the same sign as the source.

If h is not squarefree, Mathlib's proved Möbius evaluation gives μ(h)=0. This proves the stated vanishing, without assuming a squarefree-support rule.

6. Complete prime-power factorization

If gcd(g,h)=1, CRT also separates the two coordinates of u in the last sum:

$$\sum_{u\in A_q}c_h(x-u^2)c_g(x-b-u^2)=C_g(x-b)C_h(x).$$

`progression_quadratic_correlation_coprime` proves this by the actual CRT unit equivalence. The earlier prime-power factorization of C and the proved multiplicativity of μ now give the fully local expression for the normalized correlation:

$$\left(\prod_{p|g}C_{p^{v_p(g)}}(x-b)\right)\left(\prod_{p|h}\mu(p^{v_p(h)})C_{p^{v_p(h)}}(x)\right).$$

Because q=gh and gcd(g,h)=1, the two prime supports are disjoint and together cover the prime powers dividing q. Empty products have value one. The local C factors already have checked evaluations from Lemma 3.1. This completes the factorization assertion of Lemma 3.12; evaluating and summing the later Euler products of Lemma 3.14 remains a separate target.

Verification and limits

The three new modules are `LinearCohen.lean`, `ProgressionCohen.lean` and `ProgressionCorrelation.lean`. All twelve project modules build. The source scan and the transitive axiom audit of all 78 named project theorems pass, allowing only `propext`, `Classical.choice` and `Quot.sound`. No deep analytic input or additional mathematical axiom is used.

A separate exact-integer experiment checks Lemma 3.11 for every 1≤q≤128, every divisor g, every unit class b modulo g and every n modulo q: 707,264 cases, including 89,364 cases in the shared-prime branch. There are no failures. The script uses the classical integer divisor formula for Ramanujan sums and records an output digest. This is finite experimental evidence; it is not used to prove any Lean theorem.

The paper's main analytic and application theorems remain open. The formal results above certify these specified statements, not the complete paper or all of its exposition. Source-to-formal-statement correspondence must continue to be reviewed at each milestone.

`Quadratic_Oscillation_and_Abel.md`

Quadratic oscillation and actual progression Abel summation

Checkpoint 24. This is the exact partial-summation identity used in the proof of Lemma 6.5. It does not yet estimate the resulting error terms or assert a progression prime-number theorem.

The actual phase and its derivative

For real theta and real t define

$$g_\theta(t)=\exp(-2\pi i\theta t^2).$$

`quadraticOscillation` uses the real coefficient -2*pi*theta*t^2, coerced to C and multiplied by i before exponentiation. It has exactly the paper's negative phase. At every natural n it is proved equal to `negativeFourierCharacter ((n:Z)^2) (theta:PrimeCircle)`.

The offset theta is a real number here. No periodicity in theta is claimed for arbitrary noninteger t; the oscillatory integral uses the chosen real major-arc offset. The integer-indexed Fourier character agreement is proved separately.

Ordinary real differentiation, then complex coercion and the complex exponential chain rule, prove

$$g'_\theta(t) = -4\pi i\theta t\, g_\theta(t).$$

This is an actual `HasDerivAt` statement for every real theta,t. `quadraticOscillation_deriv` identifies the bundled derivative function. Both the phase and its derivative are continuous, so they are integrable on every compact real interval. No differentiability or integrability hypothesis is passed to the final Abel theorem.

The actual complex exponential has unit norm. Consequently

$$|g_\theta(t)| = 1, \qquad |g'_\theta(t)| = 4\pi|\theta||t|.$$

For 0<=t<=N this yields the explicit uniform derivative bound 4*pi*abs(theta)*N. These are unbounded Lean proofs, not numerical samples.

Actual progression coefficients and prefixes

For a natural modulus q, a residue r in ZMod q and n natural, define

$$c_{q,r}(n) = \begin{cases} \Lambda(n), & n \equiv r \pmod q, \\ 0, & \text{otherwise}, \end{cases} \qquad C_{q,r}(x) = \sum_{0\le n\le \lfloor x\rfloor} c_{q,r}(n).$$

Both are complex-valued in Lean. They are actual sums of Mathlib's von Mangoldt function; all prime powers remain. Since Lambda(0)=0, the coefficient at zero and the prefix at zero are proved to vanish.

`squareResidueSum_as_coeff` proves the exact identification

$$W_r(\theta) = \sum_{n\in S} g_\theta(n) c_{q,r}(n),$$

where W_r is the earlier unnormalized residue sum. This connects the actual residue filter to the coefficients used by Mathlib's Abel formula, including the phase and the order of complex multiplication.

The actual Abel formula

Let 0<=a<=b be reals. Applying the pinned Mathlib theorem `sum_mul_eq_sub_sub_integral_mul` to these actual coefficients and the proved differentiable phase gives

$$\sum_{\lfloor a\rfloor < n\le \lfloor b\rfloor} g_\theta(n) c_{q,r}(n) = g_\theta(b) C_{q,r}(b) - g_\theta(a) C_{q,r}(a) - \int_{(a,b]} g'_\theta(t) C_{q,r}(t)\, dt.$$

This is `progression_quadratic_abel`; `squareResidueSum_abel` rewrites its left side as the actual square residue sum. Every differentiability and derivative-integrability obligation is discharged using the proved phase lemmas. The step-function prefix is the genuine floor-indexed prefix from the Abel theorem.

Taking a=N/2 and b=N, with N natural, yields

$$\sum_{\substack{N/2<n\le N \\ n\equiv r \pmod q}} \Lambda(n) e(-n^2\theta) = g_\theta(N) C_{q,r}(N) - g_\theta(N/2) C_{q,r}(N/2) - \int_{(N/2,N]} g'_\theta(t) C_{q,r}(t)\, dt.$$

`annularMangoldtResidue_abel` proves this identity with the real lower endpoint N/2. The natural cutoff agrees because floor((N:R)/2)=N/2 in natural division; that equality is explicitly used. Thus odd N and N=0 are covered, without substituting a half-subtraction identity that requires an even cutoff. The residue sum is unnormalized; the 1/N factor is not inserted or canceled at this stage.

Files and remaining scope

Module	New named theorems	Result
QuadraticOscillation.lean	10	Actual phase, derivative, norm, continuity and integrability
ProgressionAbel.lean	6	Actual Lambda progression prefixes, residue identification and exact real-endpoint Abel formula

The next unit subtracts a differentiable model and bounds the resulting weighted prefix error, retaining both endpoints and the derivative contribution. The source model x/phi(q)-chi(r)x^beta/(beta*phi(q)) and its actual oscillatory integrals will then be specialized explicitly. The analytic prefix bound itself remains a separate published input boundary. No such theorem or own-paper deduction is assumed here.

<!-- checkpoint-verification -->

Verification

All 86 project modules and the root were freshly rebuilt: 3601 jobs pass without warnings/errors. All 717 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 88 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

Rank_Blocks_and_Finite_Bilinear.md

Corollary 4.15: constructed rank blocks and the finite bilinear estimate

Current checkpoint 20: the full abstract Corollary 4.15 is complete, including strong interior interpolation and p=2. This document records an earlier stage; see Strong_Improving_Complete.md for the completed proof and current scope.

Checkpoint 19 constructs the dyadic rank decomposition for every finite complex input and proves its coefficient mass estimate. It then proves the strong finite bilinear estimate with the exact N scaling. Three modules add 40 named theorems. **The full strong operator corollary remains partial:** finite-output norm duality and final assembly are still required.

Source correspondence and inputs

The source is Corollary 4.15 (`c:improvinggeneral`), near line 2431 of `sources/current/Draft5.tex`. Fix p0<q<p<2, where p0=2(s+r)/(2r+s). The previously proved global equation 4.17 supplies

$$|\langle T\mathbf{1}_F, \mathbf{1}_G\rangle| \le AN^{1-2/q}|F|^{1/q}|G|^{1/q}.$$

Here A is the restricted-estimate constant; B below is the norm bound of the genuine continuous l2 realization of this one kernel. They are not names of the paper's two operators. Kernel positivity is used for the complex block estimate, exactly as in checkpoint 18.

Module	Named theorems	Checked content
`DyadicRankMass.lean`	12	Rank intervals, coverage/disjointness, decreasing-sequence mass bound
`FiniteMagnitudeBlocks.lean`	25	Actual sorting, finite blocks, amplitudes, partition and coefficient mass
`FiniteBilinearImproving.lean`	3	Exact complex regrouping, coefficient norm bound, finite bilinear improving

Sorting the actual indices, including ties

Given a finite F and arbitrary f:Z->C, `decreasingMagnitudeList F f` merge-sorts the actual indices of F by decreasing |f(x)|. Its permutation, length, membership, absence of duplicate indices, and ordering properties are proved. Equal magnitudes do not require distinct values or a strict ordering. Every original index is retained, including those with f(x)=0.

Write the resulting list as x_0,...,x_(L-1), with L=|F|, and define

$$m_n = \begin{cases} |f(x_n)|, & n < L, \\ 0, & n \geq L. \end{cases}$$

`rankMagnitude_nonneg`, `rankMagnitude_antitone`, and `rankMagnitude_tail` prove that this is a nonnegative decreasing sequence with the stated zero extension. In particular, no nonempty-support assumption is introduced.

The finite rank partition

Put s_j=2^j-1 and I_j=[s_j,s_(j+1)) in the natural ranks. Then |I_j|=2^j. The intervals are pairwise disjoint, and each rank n belongs to I_(floor(log2(n+1))). For n<L, this block index is <=L.

The actual block `magnitudeBlock F f j` is the image under n->x_n of the ranks in I_j with n<L. Only j=0,...,L are needed. The construction uses a finite subset of Fin L, so no out-of-range list lookup occurs.

The proved consequences are:

- `magnitudeBlock_card_le`: |F_j|<=2^j;
- `magnitudeBlock_disjoint`: the actual finite sets are pairwise disjoint;
- `magnitudeBlock_cover`: their finite union is exactly F;
- `magnitudeBlock_sum`: summing any function over the blocks equals its sum over F, for every additive commutative monoid;
- `magnitudeBlock_norm_le`: |f(x)|<=m_(s_j) on F_j.

The amplitude is `magnitudeAmplitude F f j = m_(s_j)`. It is zero for an empty block beyond the input length. A block containing zero-valued indices also has the correct amplitude; the construction does not remove such indices. The last nonempty block may have fewer than 2^j elements.

The coefficient mass estimate

For every real p>0, set c_j=(2^j)^(1/p)*m_(s_j). The exact power identity c_j^p=2^j*m_(s_j)^p is proved, including zero amplitudes.

For the next block, all ranks n in I_j precede s_(j+1). Monotonicity gives m_(s_(j+1))^p<=m_n^p, and the full rank interval has 2^j elements. Thus

$$2^{j+1} m_{s_{j+1}}^p \leq 2 \sum_{n \in I_j} m_n^p.$$

This is `dyadic_rank_next_mass`. It holds even if part or all of the rank interval is past L: the zero extension makes those terms zero.

Induction, using the exact finite interval-sum split, proves

$$\sum_{j=0}^{K} 2^j m_{s_j}^p \leq m_0^p + 2 \sum_{n < s_K} m_n^p.$$

Every finite prefix sum of the zero-extended sequence is bounded by its original mass. This includes the prefix of length one, so m_0^p is also bounded by the original mass when L=0. Consequently

$$\sum_{j=0}^{K} c_j^p \leq 3 \sum_{n<L} m_n^p$$

for every finite K. `dyadic_rank_coefficient_mass` proves this generic statement. `rankMagnitude_sum` identifies the ranked mass with the actual sum over F by an injective, surjective finite reindexing. Specializing K=L therefore gives the actual input theorem

$$\sum_{j=0}^{|F|} c_j^p \le 3 \sum_{x\in F} |f(x)|^p.$$

This is `magnitudeBlock_coefficient_mass`. It has no assumed partition, monotonicity or coefficient estimate: all of those have been constructed and proved for the given F and f. Its p>0 range is stronger than the p>=1 range needed for the corollary.

Using the exact norm of `finiteInputLp F f P`, the theorem `magnitudeBlock_coefficient_lp_norm` proves

$$\Big(\sum_j |c_j|^p\Big)^{1/p} \le 3^{1/p} \|f\mathbf{1}_F\|_p.$$

P is an ENNReal exponent in Lean and p=P.toReal. All norms here are Mathlib's genuine sequence-space norms. The proof covers the zero vector.

Exact regrouping with complex phases

For any complex kernel K, define the actual finite pairing

$$B_{F,G}(f,g) = \sum_{x\in G}\sum_{y\in F} K(x-y) f(y)\overline{g(x)}.$$

The rank partitions of F using f and G using g give

$$B_{F,G}(f,g) = \sum_i \sum_j B_{F_i,G_j}(f,g).$$

`finiteKernelPairing_magnitudeBlocks` proves this identity by distributing the finite convolution and applying the actual block-sum identities in both variables. Complex conjugation is retained throughout. This algebraic identity needs no positivity of K; positivity enters the bound below.

The strong finite bilinear estimate

Put a=1/q-1/p and b=1/p-1/2. The previously checked actual block-family estimate gives the right side below with the coefficient norms in place of the original input norms. The new mass bounds supply one factor 3^(1/p) for each input. Thus `restricted_l2_finite_bilinear_improving` proves, for every finite F,G and arbitrary complex f,g,

$$|B_{F,G}(f,g)| \le 3^{2/p}\left(\frac{A}{1-2^{-a}} + \frac{2^b B}{1-2^{-b}}\right) N^{1-2/p} \|f\mathbf{1}_F\|_p \|g\mathbf{1}_G\|_p.$$

The formal theorem allows 1<=p<2 and 0<q<p whenever its stated global restricted q estimate holds. The paper uses p0<q<p<2. N is any positive real number. The prefactor depends on A,B,p,q and not on N, the sets, their cardinalities, the coefficients, or a chosen partition.

The theorem's analytic inputs are exactly the global restricted estimate, source kernel positivity and a genuine continuous l2 operator norm bound. It does not assume block data, a desired coefficient inequality, norm duality or strong interpolation. The earlier high-low theorem supplies the restricted estimate in the intended application. No new deep analytic theorem or mathematical axiom is used.

Remaining operator-norm step

The finite bilinear theorem is now complete. Corollary 4.15 remains partial until it is connected to the output lp' norm and both actual operators.

One proposed finite-output duality route is as follows; it is **not yet a Lean proof**. Let p'=p/(p-1)>=2 and u be the output of the coarse actual lp-to-lp' realization. On a finite output set G, use the test

$$g(x) = |u(x)|^{p'-2}u(x).$$

Then the desired identities are

$$\sum_{x\in G} u(x)\overline{g(x)} = \sum_{x\in G} |u(x)|^{p'}, \qquad \|g\mathbf{1}_G\|_p^p = \sum_{x\in G} |u(x)|^{p'}.$$

These identities, including zero coordinates and the exponent relation (p'-1)*p=p', still need formal proofs. The nonnegative p'-2 avoids a negative power at zero; p=2 can also be handled by the existing endpoint. Apply the finite bilinear estimate, split off the zero-sum case, and derive the finite output norm bound. The existing lp finite-sum norm criterion then gives the full output norm bound. Membership of u in lp' is already supplied by `lpL2Lift`.

Finally invoke `lp_opNorm_bound_of_finiteInputs` for all lp inputs, choose q between p0 and p before N, retain both original l2 constants, translate 1-2/p to 1/p'-1/p, and assemble the interior range with p=2. No assertion that these final connections are complete is made in this checkpoint.

Verification and finite experiments

All 67 modules and the root receive a fresh build with the artifact cache disabled: 3464 jobs pass without warnings or errors. All 551 named project theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 69 Lean files.

`scripts/check_dyadic_rank_blocks.py` checks 56113 finite inputs, including all 55987 input vectors of length <=6 over a six-value Gaussian integer alphabet and 126 structured longer inputs. The largest tested length is 1024. It verifies coverage, disjointness, cardinality and magnitude bounds, then 280565 coefficient mass inequalities at p=1/2,1,3/2,2,3. The alphabet has square integer magnitudes, so all tested powers are exact integers. Ties, zero inputs, empty blocks and incomplete final blocks are included.

Another 768 exact Gaussian integer checks verify complex bilinear regrouping, allowing signed and complex kernels. All pass. These finite experiments are independent checks; Lean proves the all-input statements. They do not verify output norm duality, the full operator corollary, or the later prime-square operator hypotheses.

Workspace maintenance had cleared temporary caches. The saved checkpoint 18 was recovered and all 206 archive entries were verified. The exact Lean 4.34.1 release archive hash and pinned dependency revisions were verified before rebuilding. No version upgrade or proof-kernel change was made. The archived manuscript and accepted revision fragments are unchanged. The count of completely proved unconditional numbered results remains nine; Lemma 3.21 retains its earlier explicit PNT hypotheses independently.

`Rational_Arc_Separation.md`

Exact rational-arc separation

For integers a,b and positive q,r, a nonzero determinant $ar - bq$ gives

$$|a/q - b/r| \geq 1/(qr).$$

The proof casts the nonzero integer determinant to the reals, proves its absolute value at least one, and divides by the positive denominator product.

For rationals u,v with their reduced positive denominators, this yields

$$u \neq v \Longrightarrow |(u : \mathbb{R}) - (v : \mathbb{R})| \geq 1/(\mathrm{den}(u)\,\mathrm{den}(v)).$$

If u,v are distinct canonical representatives in [0,1), the same lower bound holds for $|u - v - k|$ for every integer k. An equality u=v+k would force -1<k<1, hence k=0 and u=v. This accounts explicitly for integer lifts when an arc crosses the boundary of a fundamental interval.

If both denominators are at most D, separation is at least $1/D^2$. Two real arcs of radius delta centered at distinct such rationals cannot contain a common point when $2\delta < 1/D^2$. The final theorem proves that uniqueness from the triangle inequality.

Module	New named theorems
RationalArcSeparation.lean	6

Scope

These are exact unconditional proofs. No numerical sampling is used. Dyadic support uniqueness will only be asserted when its strict radius inequality is proved; the smallest denominator scales will not be silently included by an inapplicable estimate. The analytic minor-arc gap remains unchanged.

<!-- checkpoint-verification -->

Verification

All 101 project modules and the root were freshly rebuilt: 3616 jobs pass without warnings/errors. All 800 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 103 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Ren_Input_and_Annular_Bound.md`

Ren's actual annular sum and a verified minor-arc consequence

Checkpoint 31. This unit connects the paper's genuine negative-phase annular Fourier sum to Ren's positive-phase sum, transports the exact three-term bound, and proves a valid decay consequence in an explicit parameter range. It leaves the manuscript's wider minor-arc claim open.

Published input and its scope

The primary text inspected is Xiumin Ren's author preprint, On exponential sum over primes and application in Waring-Goldbach problem, Theorem 1.1, corresponding to the cited 2005 paper. Its sum is already over x<m<=2x. For k=2, frequency xi=a/q+theta and reduced a/q, its displayed bound has the form

$$|S(x,\xi)| \le C\tau(q)^{3/2}(\log x)^A\left(\sqrt{x}\sqrt{T}+x^{4/5}+\frac{x}{\sqrt{T}}\right), \qquad T=q(1+|\theta|x^2).$$

Here C,A are fixed constants supplied by the analytic result. The exact journal text was not accessible; the author-hosted preprint's statement and first-page formula were checked. This result itself is not proved in Lean or added as an axiom. The consuming theorems display the actual inequality as a hypothesis. External applicability requires x in the theorem's large-parameter range and the stated rational approximation.

Actual sum, sign and endpoints

`renQuadraticSum` is the complex finite sum of Lambda(n)*e(xi*n^2) over floor(x)<n<=floor(2x). `renQuadraticSum_exp` identifies the exact positive complex exponential explicitly. Conjugation of this actual sum reverses the sign of xi and preserves its norm, because Lambda is real. These are proved identities, not assumed Fourier conventions.

Taking x=N/2 uses the real lower endpoint, with floor(N/2)=N/2 in natural division and floor(2*(N/2))=N. Thus for every natural N,

$$\widehat{\widetilde{A}}_{N,\Lambda}(\xi)=\frac{1}{N}S(N/2,-\xi), \qquad \left|\widehat{\widetilde{A}}_{N,\Lambda}(\xi)\right|=\frac{1}{N}|S(N/2,\xi)|.$$

These identities even handle odd N and the inverse convention at N=0. Applying the external analytic theorem requires N sufficiently large; the explicit source-prefactor corollary below uses N>=4. No prime powers are dropped. There is no need to reconstruct this annular sum by subtracting two initial sums.

Exact bound transported to the annulus

Put B=C*tau(q)^(3/2)*(log x)^A and

$$J(x,T)=\sqrt{x}\sqrt{T}+x^{4/5}+x/\sqrt{T}.$$

`annularMangoldt_from_Ren_bound` proves directly from the raw inequality |S(N/2,xi)|<=B*J(N/2,T) that

$$\left|\widehat{\widetilde{A}}_{N,\Lambda}(\xi)\right| \le \frac{B}{N}J(N/2,T).$$

This retains all three terms and every normalizing factor. The theorem does not assert that arbitrary independent choices of xi,theta,q satisfy the analytic input: the genuine raw inequality is displayed.

A proved decay range

For x>0, R>0, assume

$$R \le T \le x/R, \qquad R \le x^{2/5}.$$

Then each term of J(x,T) is at most x/sqrt(R). Indeed:

1. T*R<=x implies sqrt(T)*sqrt(R)<=sqrt(x), and hence sqrt(x)*sqrt(T)<=x/sqrt(R).
2. R<=x^(2/5) implies sqrt(R)<=x^(1/5), giving x^(4/5)*sqrt(R)<=x.
3. T>=R implies x/sqrt(T)<=x/sqrt(R).

Thus `ren_bracket_central_bound` proves J(x,T)<=3*x/sqrt(R). The exact N=2x normalization gives

$$\left|\widehat{\widetilde{A}}_{N,\Lambda}(\xi)\right| \le \frac{3B}{2\sqrt{R}}.$$

`annularMangoldt_Ren_central_source` substitutes the actual divisor and logarithmic prefactor and T=q*(1+abs(theta)*(N/2)^2). Its positivity is proved using N>=4 and C>=0. The divisor factor multiplies the whole bound; it has not been discarded or silently absorbed into a logarithm.

The remaining source deduction

The manuscript's Lemma 6.5 asks for a minor-arc estimate throughout R^(11/10)<q<=N^2/R with abs(theta)<=R/(q*N^2). Those conditions do not imply the central-range hypothesis T<=x/R. For example, theta=0 and q comparable to N give T comparable to x. At T=x, the first normalized term in Ren's displayed estimate is exactly

$$\frac{\sqrt{x}\sqrt{T}}{x} = 1.$$

`ren_first_term_diagonal` proves this identity for every x>0. Thus direct substitution into this particular bound does not supply a decaying estimate in the entire source range. A further argument or a complementary estimate must be supplied and checked. This is a gap in the currently verified deduction, not a counterexample to the manuscript's minor-arc assertion. No replacement of that assertion is prescribed on this evidence alone.

The conditional source-range major-arc R^-5 theorem remains intact. Full Lemma 6.5 stays open pending its independent full-range minor-arc argument and the precise external-input bridge. Proposition 4.19 and the paper's Theorem 1.1 remain explicit later targets.

Module	New named theorems	Result
RenSumCompatibility.lean	6	Positive-phase exponential, conjugation, exact floor endpoints and actual annular normalization
RenMinorArcBound.lean	5	Raw Ren bound transport, proved central-range decay with actual prefactor, and the diagonal diagnostic

All new deductions are Lean proofs. Ren's deep estimate is a displayed theorem hypothesis, with no new mathematical axiom or proof placeholder.

<!-- checkpoint-verification -->

Verification

All 96 project modules and the root were freshly rebuilt: 3611 jobs pass without warnings/errors. All 771 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 98 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Ren's displayed three-term estimate enters only as an explicit hypothesis of conditional consuming theorems; it is not added as an axiom. No own-paper lemma is assumed.

Residue_Grouping_and_Major_Arc_Assembly.md

Residue grouping and finite major-arc assembly

Checkpoint 23. Source: Draft5, proof of Lemma 6.5 (`l:prime-square-input`), immediately after `e:prime-square-minor-input`. This unit proves the finite residue decomposition, controls the discarded non-unit terms, and assembles the ordinary and twisted Gauss factors with explicit error accounting. The full major-arc and minor-arc statements of Lemma 6.5 remain open.

Actual sums and conventions

For finite S contained in {1,...,N}, real c and real weights w, the already constructed continuous Fourier symbol is

$$m_{S,c,w}(\xi) = c\sum_{n\in S} w(n)e(-n^2\xi).$$

The actual annular von Mangoldt symbol takes S = {floor(N/2)+1,...,N}, c = 1/N and w(n) = Lambda(n), including every prime power. Frequencies are in the period-one additive circle. Finite regrouping works for every positive modulus q and every integer numerator a; no coprimality or major-arc size restriction is needed for these algebraic identities.

Define the unnormalized residue sum

$$W_r(\theta) = \sum_{\substack{n\in S\\ n\equiv r \pmod q}} w(n)e(-n^2\theta).$$

This is `squareResidueSum`. It is a finite sum using the actual equality of natural-number casts in ZMod q. The normalization c is kept outside W_r, so it cannot be silently applied twice.

Non-unit support and its sharper elementary bound

If Lambda(n) is nonzero, Mathlib's actual von Mangoldt definition implies n = p^k for some prime p and k >= 1. If n is not coprime to q, then p must divide q: otherwise p is coprime to q, hence so is p^k. `mangoldt_nonunit_prime_power` proves this support statement.

Split the non-unit mass into primes and non-primes. For the prime part, only distinct primes dividing q can occur. Therefore

$$\sum_{\substack{n\in S\\ n \text{ prime}\\ (n,q)>1}} \Lambda(n) \le \sum_{p\mid q} \log p \le \log q, \qquad q>0.$$

The last inequality is the already proved `primeFactors_log_budget`: the product of the distinct primes dividing q divides q. The finite-set inclusion and the use of the actual prime value Lambda(p)=log(p) are proved in `mangoldt_prime_nonunit_mass_le_log`.

For all the non-prime terms, including those coprime to q, the pinned Mathlib identifies the full weighted mass with psi(N)-theta(N), then proves the elementary estimate

$$0 \le \psi(N) - \vartheta(N) \le 2\sqrt{N}\log N, \qquad N\ge 1.$$

The exact declarations are `Chebyshev.psi_sub_theta_eq_sum_not_prime` and `Chebyshev.psi_sub_theta_le`. By nonnegativity of Lambda, any subset of the higher prime powers has at most this mass. Our `mangoldt_nonprime_mass_bound` proves that subset implication.

Combining the two parts gives, for every S contained in {1,...,N},

$$0 \le \sum_{\substack{n\in S\\(n,q)>1}} \Lambda(n) \le \log q + 2\sqrt{N}\log N.$$

This is `mangoldtNonunitMass_le`. N >= 1 and q > 0 are its only size restrictions. For q=1 the discarded set is actually empty; `mangoldtNonunitMass_one` records exact vanishing.

The source uses the looser normalized error O(N^(-1/2)(log N)^2 + q N^(-1)(log N)^2). The proved explicit estimate above is sharper and is sufficient for this reduction step. It does not require changing the source statement. No PNT or distribution-in- progressions estimate is used; the Chebyshev bound is already proved in the same pinned Mathlib.

The exact residue identity

For every integer n and circle offsets alpha,beta, the negative Fourier character obeys c_n(alpha+beta)=c_n(alpha)c_n(beta). At a rational frequency we already know c_(n^2)(a/q)=stdAddChar_q(-a*n^2). We prove and apply the argument-addition identity, obtaining

$$e(-n^2(a/q+\theta)) = e(-an^2/q)e(-n^2\theta).$$

Within the class n congruent to r modulo q, the first factor is exactly e(-a r^2/q). Each natural n lies in one and only one residue class, so finite interchange of summation gives

$$m_{S,c,w}(a/q+\theta) = c\sum_{r\in\mathbb{Z}/q\mathbb{Z}} e(-ar^2/q)W_r(\theta).$$

`finite_sum_residue_fibers` proves the partition identity and `finiteSquareSymbol_residues` applies the actual rational phase.

A natural-number cast is a unit in ZMod q exactly when it is coprime to q. This proves that restricting S to the coprime n retains W_r precisely for unit r and makes it zero for other r. The earlier exact equivalence between the unit-filter convention and the actual unit group then gives

$$m_{S,c,w}(a/q+\theta) = c\sum_{r\in(\mathbb{Z}/q\mathbb{Z})^\times} e(-ar^2/q)W_r(\theta) + \mathcal{E}_{\text{nonunit}},$$

where the remainder is explicitly

$$\mathcal{E}_{\text{nonunit}} = c\sum_{\substack{n\in S\\(n,q)>1}} w(n)e(-n^2(a/q+\theta)).$$

This is `finiteSquareSymbol_reduced_residues`. It retains an equality with an actual finite remainder, rather than replacing the remainder by an unexplained big-O term.

For nonnegative c and weights, the triangle inequality and unit magnitude of every Fourier character give

$$|m_{S,c,w}(\xi)| \le c\sum_{n\in S} w(n).$$

Together with the mass estimate, this proves, for the actual annular Lambda symbol and N >= 1,

$$\left|\widehat{\widetilde{A}}_{N,\Lambda}(a/q+\theta) - \frac{1}{N}\sum_{r\in(\mathbb{Z}/q\mathbb{Z})^\times} e(-ar^2/q)W_r(\theta)\right| \le \frac{\log q + 2\sqrt{N}\log N}{N}.$$

`annularMangoldt_reduced_residues_bound` is this unbounded, uniform-in- frequency Lean theorem. Its q=1 remainder is exactly zero. The finite identities also cover empty S and the total N=0 definition; the logarithmic inequality is stated only for N >= 1.

Ordinary and twisted Gauss assembly

Fix q>0, an arbitrary complex Dirichlet character chi modulo q, and two complex numbers M_1 and M_beta. In a future application these will be the ordinary and exceptional oscillatory integrals. No assertion about those integrals or a progression asymptotic is assumed in this unit.

For each residue r define its actual normalized model error by

$$\varepsilon_r = cW_r(\theta) - \frac{1}{\varphi(q)}(M_1 - \chi(r)M_\beta).$$

The function `squareResidueModelError` is exactly this difference. In the Lean declaration the scalar names are `M,E`; they denote M_1,M_beta here. That scalar E is separate from both the non-unit remainder and the paper's global error operator E_(Q,N).

The Section 3 Gauss definitions have already fixed

$$\mathfrak{s}(a,q) = \frac{1}{\varphi(q)} \sum_{r\in(\mathbb{Z}/q\mathbb{Z})^\times} e(-ar^2/q), \quad \mathfrak{s}_\chi(a,q) = \frac{1}{\varphi(q)} \sum_{r\in(\mathbb{Z}/q\mathbb{Z})^\times} \chi(r)e(-ar^2/q).$$

Distributivity of these actual finite sums gives

$$\sum_r e(-ar^2/q)\frac{M_1 - \chi(r)M_\beta}{\varphi(q)} = \mathfrak{s}(a,q)M_1 - \mathfrak{s}_\chi(a,q)M_\beta.$$

This is `unitSquareGauss_model_identity`. Combining it with the exact residue decomposition and the definition of epsilon gives the identity

$$m_{S,c,w}(a/q+\theta) - (\mathfrak{s}(a,q)M_1 - \mathfrak{s}_\chi(a,q)M_\beta) = \mathcal{E}_{\text{nonunit}} + \sum_r e(-ar^2/q)\varepsilon_r.$$

`finiteSquareSymbol_majorArc_error_identity` proves this formula for all of the displayed data, without an approximation hypothesis. It preserves the exceptional minus sign and the exact totient normalization.

Taking norms gives the sum of the actual residue-error norms. For the annular Lambda average this is

$$\left|\widetilde{A}_{N,\Lambda}(a/q+\theta) - (\mathfrak{s}(a,q)M_1 - \mathfrak{s}_\chi(a,q)M_\beta)\right| \le \frac{\log q + 2\sqrt{N}\log N}{N} + \sum_r |\varepsilon_r|.$$

If a later argument proves |epsilon_r| <= delta on every unit residue, there are exactly phi(q) such residues. The final theorem therefore gives

$$\text{error} \le \frac{\log q + 2\sqrt{N}\log N}{N} + \varphi(q)\delta.$$

The per-residue bound is an explicit hypothesis of this last implication; it has not been established by naming the errors. The preceding identity and sum-of-errors inequality have no such hypothesis. Without an exceptional contribution one can put M_beta=0. All assertions are at an individual scale, and do not freeze exceptional data as N varies.

Files and proof scope

Module	New named theorems	Completed work
MangoldtNonunits.lean	6	Actual non-unit prime-power support and logarithmic/Chebyshev mass bound
SquareResidueGrouping.lean	8	Exact rational shift, full residue partition and unit-group decomposition
MangoldtResidueReduction.lean	4	Uniform explicit remainder for the actual annular Lambda symbol
SquareMajorArcAssembly.lean	5	Exact ordinary/twisted Gauss assembly and finite error accounting

These are 23 supporting theorems. They complete these finite proof steps, not either full numbered conclusion of Lemma 6.5. The ten completed numbered paper results are unchanged. No own-paper lemma or new deep analytic input has been assumed.

The full fresh artifact-cache-disabled build passes 3599 jobs, with all 84 modules and the root rebuilt and no warnings/errors. All 701 named project theorems pass the complete transitive whitelist: propext, Classical.choice and Quot.sound. The source scan checks 86 Lean files; there are no placeholders or added mathematical axioms. No dependency version was changed and no new Mathlib cache target was required.

Independent finite checks

`scripts/check_residue_grouping.py` checks 18144 finite residue identities and 18144 corresponding Gauss/error identities. It uses q=1,...,12, N=0,...,8, full and annular windows, ordinary/Lambda/signed weights, negative and positive numerators, offsets 0,1/2,-1/3,1/4, and principal or available induced real characters. Both a nonzero exceptional model and a zero exceptional model are tested.

Coefficients are exact Gaussian rationals and independent formal log(prime) symbols in a cyclic group algebra, with order the lcm of the frequency denominators. There is no transcendental evaluation or floating point. The identities hold at the formal coefficient level, hence under the usual root-of-unity evaluation. These tests complement the Lean proofs; they are not an unbounded mathematical proof.

Separate probes check 395 non-unit prime-power support instances and 576 divisibility cases for the product of prime divisors in a cutoff. The support/product ranges are q<=64 and n<=128. At N=4,q=2 the omitted annular non-unit term is log(2)/4 from n=4. At q=5 a reversed exceptional sign changes the Gauss/error identity. The q=1 and N=0,1 cases, and odd cutoffs, are explicitly included.

The tests do not numerically certify the logarithmic/Chebyshev inequality, a progression estimate, partial summation, an R^-5 error, or a maximal estimate. The general finite remainder bound is a Lean proof using Mathlib's proved Chebyshev inequality.

Next obligations

1. Prove partial summation for the actual progression-weighted Lambda sums with the quadratic oscillation. The prefix-error bounds and endpoint terms must yield the correct normalized error, including theta*N^2. Mathlib.NumberTheory.AbelSummation already supplies the general Abel formula; inspect and reuse it before rebuilding infrastructure.
2. Verify and state the exact published prime-distribution and minor-arc input boundaries, with uniform constants and parameter ranges. One scale's exceptional data must work throughout the prefix interval [N/2,N], while it may change between scales.
3. Specialize M_1,M_beta to the actual source integrals, differentiate t^beta/beta correctly, and derive the per-residue error bounds.
4. Prove the final R^-5 major-arc bound in the permitted N,Q,R ranges and the annular minor-arc statement, completing Lemma 6.5.
5. Continue approximation 6.9, low 6.14, multifrequency 6.16, high/maximal 6.21, Proposition 4.19 and the Theorem 1.1 application.

Exceptional conductor, character and beta may depend on N. Published deep inputs may be explicit hypotheses, as authorized, but the paper's own partial summation and deductions remain proof obligations. Lemma 3.21's two earlier PNT limits are unchanged and unused in this unit. The frozen manuscript and both accepted revisions are unchanged; no new source correction is pending.

`Restricted_Improving.md`

Corollary 4.15: global restricted improving and weak distribution bounds

Current checkpoint 20: the full abstract Corollary 4.15 is complete, including strong interior interpolation and p=2. This document records an earlier stage; see Strong_Improving_Complete.md for the completed proof and current scope.

Checkpoint 16 proves equation 4.17 (`e:restrictedimproving`), including its exact N scaling, from Theorem 4.1 and the stated extra l2 bounds. It also proves the actual restricted weak distribution estimate and the strong p=2 case for the unique continuous linear l2 realizations.

The strong estimate for p0<p<2 in Corollary 4.15 is still open. The interpolation step for general lp inputs is not a hypothesis or an axiom in this project. This checkpoint does not mark the whole corollary complete.

Source and exact statement

The source is `c:improvinggeneral`, Corollary 4.15, beginning near line 2431 of `sources/current/Draft5.tex`. Equation 4.17 is the restricted pairing estimate inside its proof. Equation 4.16 (`e:lpimproving`) is the full strong conclusion and remains only partially covered.

Put

$$p_0 = \frac{2(s+r)}{2r+s}, \qquad p' = \frac{p}{p-1}.$$

For every p0<p<=2, `highLow_AB_restricted_improving` proves that one D>0, quantified before N, both kernels, windows and F,G, satisfies

$$|\langle A_N 1_F, 1_G\rangle| + |\langle B_N 1_F, 1_G\rangle| \le D N^{1/p'-1/p} |F|^{1/p} |G|^{1/p}$$

for every positive real N and all finite F,G in the integers. There is no remaining cardinality-product or common-interval restriction. In particular, the sum estimate gives the source's estimate for each operator separately. Empty input and test sets are included.

The hypotheses are the completed Theorem 4.1's actual abstract operator inputs and two genuine uniform continuous linear l2 realizations. Their l2 constants may be different. This result does not establish the prime-square operator hypotheses.

Four new modules

Module	Checked content
`RestrictedPowers.lean`	Critical/conjugate exponent algebra, exact density scaling, uniform removal of losses, zero density
`RestrictedL2.lean`	Actual continuous linear l2 inputs, uniqueness, strong p=2 case, l2 pairing bound and globalization
`RestrictedImproving.lean`	Equation 4.17 for both actual kernels and all finite sets
`RestrictedWeak.lean`	Finiteness of positive superlevel sets, weak gauge/cardinality bounds and both-kernel restricted weak theorem

They add 33 named theorems. The completed Theorem 4.1 and its scalar optimization are reused rather than assumed in a new conditional statement.

Exact exponents and normalization

For s,r>0, the following identities and inequalities are proved:

$$1 < p_0 < 2, \qquad \frac{1}{p_0} = 1 - \frac{s}{2(s+r)} =: \theta, \qquad \frac{1}{p'} = 1 - \frac{1}{p}.$$

Thus p>p0 gives epsilon=theta-1/p>0. For p<=2, `1/2<=1/p`. The definitions are `improvingCriticalExponent` and `holderConjugate`. Positivity and nonvanishing needed in the divisions are checked before using these formulas.

For N>0 and nonnegative real f,g, the exact scaling identity is

$$N\left(\frac{fg}{N^2}\right)^{1/p} = N^{1-2/p} f^{1/p} g^{1/p} = N^{1/p'-1/p} f^{1/p} g^{1/p}.$$

This is proved for real powers, including f=0 or g=0. It is used to convert the normalized density estimate into the literal N power in equation 4.17. No unspecified comparison or hidden N-dependent constant is involved.

Uniform removal of the endpoint losses

The B_N endpoint has factor `(Log delta)^tau`, with the exact tau from Theorem 4.1. The A_N endpoint has Phi(cstar,kappa,delta). For any sigma<theta with sigma>0, the new modules prove, with constants uniform on 0<=delta<=1,

$$\delta^\theta (\mathrm{Log}\,\delta)^\tau \le C\delta^\sigma, \qquad \delta^\theta \Phi_{cstar,\kappa}(\delta) \le C'\delta^\sigma.$$

For positive delta these follow from the already proved uniform Phi sub-power bound, with epsilon=theta-sigma. A fixed logarithmic power is first absorbed into Phi(1,1/2,delta). At zero, positivity of theta and sigma makes both density powers vanish. This zero case is proved separately; there is no limiting substitution at log(0).

The A_N coefficient is chosen once as the printed leading coefficient plus one. Theorem 4.1 allows that choice, and the final restricted estimate is independent of density. Taking sigma=1/p gives `highLow_AB_power_small` for |F||G|<=N^2. It retains actual operator inputs through `HighLowEndpointInputs` and does not assume an endpoint deduction.

The genuine l2 hypothesis

`KernelL2Bound K C` means there exists a continuous complex-linear map

$$T : \ell^2(\mathbb{Z}) \longrightarrow \ell^2(\mathbb{Z})$$

with operator norm at most C, whose value on every finite indicator agrees pointwise with the actual convolution by K. This is the restriction of the source's uniform l2 convolution bound needed here. The source operator itself supplies the map.

`kernelL2_realization_unique` proves that two such maps agree on the whole l2 space. Agreement on singleton indicators gives agreement on their complex multiples; Mathlib's proved density of finite-support vectors and continuity then give equality. Thus the realization is determined by the kernel.

`kernelL2_pair_strong_two` supplies both realizations and proves

$$\|T_A f\|_2 + \|T_B f\|_2 \le (C_{2,A} + C_{2,B})\|f\|_2 \quad (f \in \ell^2).$$

Since p'=2 at p=2 and the N exponent is zero, this is the strong p=2 case. The interior p0<p<2 still requires interpolation.

Larger cardinality products

The actual l2 input and the proved indicator norm identities imply

$$|\langle T1_F, 1_G\rangle| \le C_2\sqrt{|F|}\sqrt{|G|}.$$

After division by N this is `C2*delta^(1/2)`. If |F||G|>N^2, then delta>1; since p<=2, real-power monotonicity gives `delta^(1/2)<=delta^(1/p)`. This proves the same normalized restricted bound in the missing range. The small-range and l2 constants are added before N,F,G are introduced.

The result is global in F,G. This provides an alternative first step for the source's interpolation/localization proof; no finite-propagation or interval partition theorem is needed for this restricted deduction. The subsequent strong argument remains to be established.

Actual superlevel sets and restricted weak type

For a nonnegative kernel K and a positive level lambda, let

$$E = \{x : \lambda < |T1_F(x)|\}.$$

`kernelL2Bound_superlevel_finite` proves that E is finite: the l2 output has summable squared norms, those squares tend to zero along the cofinite filter, and only finitely many can exceed lambda squared.

Every output is real and nonnegative. The earlier exact positive pairing identity therefore gives

$$\lambda|E| \le |\langle T1_F, 1_E\rangle| \le S|F|^{1/p}|E|^{1/p}, \qquad S = DN^{1/p'-1/p}.$$

For nonempty E the proof divides by the strictly positive power `|E|^(1/p)` and uses `1/p'+1/p=1`. The empty case is handled directly. The result is

$$\lambda|E|^{1/p'} \le S|F|^{1/p}, \qquad |E| \le \left(\frac{S|F|^{1/p}}{\lambda}\right)^{p'}.$$

The Lean result constructs an actual finite set E, proves its membership is equivalent to the displayed superlevel condition on the whole integer line, and proves the weak gauge inequality. `weak_gauge_to_`

`cardinality` proves the cardinality conversion. `highLow_AB_restricted_weak` connects this to both kernels and all the actual source norm assumptions.

The positivity of A_N is used in this distribution step, as supplied by the original theorem. The global complex pairing estimate itself did not need that additional positivity. These are indicator-input weak bounds; they are not a strong estimate for general inputs.

Verification and numerical scope

The project now has 58 modules and 457 named theorem declarations; the source scan covers 60 Lean files. All modules and the root receive a fresh build, with the artifact cache disabled. All named theorem declarations receive the complete transitive axiom audit with whitelist propext, Classical.choice and Quot.sound. See the current verification logs.

The new exact experiment checks 11250 normalization cases, including 882 zero-product cases and 9303 larger-density cases. It examines 98304 distinct finite positive-kernel pairings at three conjugate exponents (294912 pairing/exponent checks), and 36864 superlevel inequalities. Empty superlevels and strict-threshold boundary cases are included. All pass.

The finite families use six integer kernels, all input subsets of {-2,-1,0,1,2}, all output subsets of {-4,...,4}, and positive half-integer levels. The normalization exponents are p=4/3,3/2,2. Integer powers remove all radicals, so the checks use only integers and exact fractions. These finite checks do not verify the unbounded analytic operator hypotheses or the missing strong interpolation theorem. General real-parameter restricted implications are proved in Lean.

No new mathematical axiom, deep input or manuscript correction is used. The explicit PNT hypotheses in Lemma 3.21 remain independent.

Remaining obligation

The nine fully proved numbered results, including Theorem 4.1, remain unchanged. Corollary 4.15 is partial: equation 4.17, the actual restricted weak consequence and p=2 are proved; the strong interior range is open.

Checkpoint 17 connects finite complex inputs, genuine lp operator realizations, uniqueness and density, and proves the finite Schur lemmas; see `Strong_Interpolation_Foundations.md`. The strong interpolation estimate with the correct N scaling still needs to be proved. Checkpoint 18 also closes the actual geometric weight and complex block/family estimates; see `Interpolation_Geometry.md`. The rank construction, mass bound, finite-output duality and final strong assembly remain open. The local source search did not find a named Marcinkiewicz/Riesz--Thorin/restricted-weak theorem in the pinned Mathlib; that search is recorded in `verification/interpolation-availability.json`. This is a search result, not a proof that no suitable result exists under another name. A concrete proposed construction is recorded in `blueprint/Strong_Interpolation_Plan.md`; it distinguishes checked supporting steps from the remaining unproved construction, with no Lean placeholders added.

Checkpoint 19 constructs the rank blocks, proves the mass bound and derives the strong finite bilinear estimate. See `Rank_Blocks_and_Finite_Bilinear.md`. Finite-output norm duality and final strong operator assembly remain open.

`Section11_Complete.md`

Section11 is complete for the reviewed corrected statements. The joint endpoint goldbach_section11_complete uses one B,C for the actual lower and upper sieve counts, actual common main term, the lower bound k N(log N)^(-(A0/2+6)), and both original remainder families. It gives the exact lower coefficient f_(1/2)(9/8), the exact upper coefficient c_(9/8) F_1(2) W(9/8), uniform tolerances, coefficients chosen before n and a combined mean-square saving of arbitrary logarithmic order. C can exceed any prescribed minimum and C>=A0+24 is sufficient. The exponent A0/2+6 is independent of C. Strict positivity of the normalized coefficient difference is already kernel checked.

The general one-stage sieve, SW/BV, Ren/Ghosh, effective multiplicative mean and classical Mertens inputs, plus classical sieve-function continuity and normalization, remain explicit independent hypotheses. No paper endpoint is an input or an added mathematical axiom.

A complete replacement copy is saved as sources/review/Section11_Reconciled.tex. It applies the earlier presieving hypotheses and endpoint correction, both lower-bound notation fixes, the weighted integration correction, the inclusive p2=z endpoint in both occurrences, and a shorter exact numerical-comparison proof matching Lean. Original manuscript files and their accepted hashes remain unchanged. The generated copy has unique labels and balanced environment counts; it has not been typeset

as a standalone document. The reproduction script and exact replace-with manifest are included.

Crucial source distinction: the weaker original l:presieving hypothesis is not claimed proved. Its completed claim now points explicitly to the separately supplied corrected statement, whose bytes and original-statement bytes are guarded by hashes. The user manuscript still requires those edits. This review-copy completion does not assert that the user has applied them. The remaining open paper-level claim is the final quantitative Goldbach theorem; the original presieving version is retained as a superseded, unclaimed variant.

The weighted endpoint uses the checked effective upper-mean route. It does not add completion credit to every stronger asymptotic displayed in the manuscript's alternative convolution argument. The exported lemma conclusions and the joint sieve estimates are what is certified.

`Section11_Fixed_Sieve_Comparison.md`

Section 11: fixed sieve sets and progression sequences

This note explains the checked starting results through checkpoint1218. It does not claim the later local-density, presieving or final sieve propositions.

Actual sets

The lower sequence consists of integers r-1, where r is prime, r=11 modulo24 and n-r is a prime square. The original sieve uses primes p=3 modulo4 which do not divide n-1. The fixed sieve uses all primes p>3 with p=3 modulo4. Both use the strict real cutoff p<z.

The upper sequence M_n(ell) consists of integers r=ell*t+1<N² with t a prime congruent to3 modulo4 and n-r=m² for a prime m>3. The original upper sieve primes do not divide12*ell*n. The fixed upper sieve primes do not divide12*ell. The level is exactly (N²/ell)^(1/4). The actual closed multiplier set L and its subset L_n are retained.

These definitions are implemented as `goldbachFixedLowerSiftedValues`, `goldbachFixedUpperSifted` and the previously proved original sets. No formal set is replaced by a generic counting hypothesis.

Lower comparison

For every lower-sequence element, r-1=10 modulo24, so3 does not divide r-1. Every other prime in the original lower sieve belongs to the fixed prime set. Surviving the fixed sieve therefore implies surviving the original sieve. Taking cardinalities gives exactly the source lower inequality. The shift from r to r-1 is implemented on actual finite sets.

Checked declarations: `goldbach_fixed_lower_subset`, `goldbach_fixed_lower_values_subset`, `goldbach_fixed_lower_count`.

Exact upper exceptional count

Suppose a pair (ell,r), with ell in L_n, survives the original upper sieve but fails the fixed sieve. Some prime p below the actual level divides r and does not divide12*ell. If p did not divide n, it would be an original upper sieve prime, contradicting survival. Thus p divides n.

Write n-r=m² using the actual defining prime m of M_n(ell). Since p divides both n and r, p divides m². Primality gives p=m, hence r=n-p². Also r-1=ell*t>0, so ell divides the positive integer n-p²-1.

For a fixed p dividing n, the number of such multiplier pairs is therefore at most tau(n-p²-1). Summing gives the exact finite inequality

$$\sum_{\ell\in L_n} S(M_n(\ell),W_{\ell,n},z_\ell)\le\sum_{\ell\in L} S(M_n(\ell),W_\ell,z_\ell)+\sum_{p\mid n}\tau(n-p^2-1).$$

The proof counts pairs (ell,r), so multiplicities across different multipliers are retained. Enlarging L_n to L is handled by a proved finite-set inclusion. Divisor arguments equal to0 contribute0 in the finite envelope; every actual exceptional pair has a positive divisor argument.

Checked declarations: `goldbach_fixed_upper_exception`, `goldbach_fixed_sieve_exceptions_card`, `goldbach_fixed_upper_source_count_finite`.

Uniform power error

For each epsilon>0, the elementary prime-factor bound gives a constant K1 such that the number of prime divisors of n is at most K1 N^(epsilon/2), uniformly for positive n<=N². The proved divisor bound

gives a constant K2 such that tau(a)<=K2 N^(epsilon/2) for every0<=a<=N². Both constants are chosen before N and n.

Applying the second bound to each n-p²-1 gives

$$\sum_{p|n} \tau(n-p^2-1) \le K_1 K_2 N^{\varepsilon}.$$

The actual proof covers every N>=1,0<n<=N² and every real z, which contains the full retained source range. Neither PNT nor a sieve theorem is used. This closes the whole source lemma `l:fixedsievesets10`, not merely a numerical instance or an implication from the desired error bound.

Checked declarations: `goldbach_uniform_divisor_card`, `goldbach_fixed_sieve_divisor_sum`, `goldbach_fixed_sieve_sets`.

Lower progression identity

For a positive d whose prime divisors exceed3, the CRT supplies a coprime class a modulo24d satisfying a=11 modulo24 and a=1 modulo d. For every prime r, these two conditions are equivalent to r=a modulo24d and d dividing r-1.

The actual lower divisibility count is therefore exactly the number of prime pairs m,r with m²+r=n and r=a modulo24d. The finite count bijection is proved; uniqueness of the positive prime m follows from injectivity of squaring. The residue a is chosen before every n.

Using the actual definition of the already proved circle-method remainder then gives the exact G_R H_R/phi(24d) plus remainder decomposition. Normalizing this by the source X_n and omega_n still requires the local-density calculation, which remains open.

Checked declarations: `goldbach_lower_sieve_sequence_count`, `goldbach_lower_sequence_fixed_residue`, `goldbach_lower_sequence_circle_identity`.

Upper progression identity

For ell in the actual closed L and z>3, the source factorization ell=2*u*p2 gives ell=2v with v=3 modulo4 and coprime to6. This is proved from the prime support of u and the primality and lower bound of p2.

For d coprime to12*ell, the upper CRT class a modulo12d satisfies v*a=5 modulo12 and ell*a+1=0 modulo d. The congruence t=a modulo12d is proved equivalent to these two conditions with t in place of a.

For n=12 modulo24, the equation m²+ell*t=n-1 and this residue condition force m>3 and t=3 modulo4. Conversely, the actual defining conditions of M_n(ell) yield that residue condition. The proof therefore gives the exact finite identity at n-1, including the source prime exclusions and the actual r<N² cutoff. Again a is chosen before every n.

Checked declarations: `goldbach_upper_sieve_sequence_count`, `goldbach_closed_multiplier_residue_data`, `goldbach_upper_sequence_fixed_residue`, `goldbach_upper_sequence_circle_identity`.

Mean-square remainder transport

Let I be any fixed finite subset of the allowed circle-method indices. Extend its coefficients by0 outside I and extend the residue family by the coprime representative1. The full circle-method theorem applies to these extended families. A checked finite sum identity removes every added index and recovers the sum over I exactly. The constant and threshold retain their original order before all families and cutoffs.

For the upper sieve, n maps to n-1 injectively on positive integers. Thus a sum over any positive subset of n<N² is bounded by the full original mean-square sum. If the whole range0<=n<N² is used, the value at0 is counted twice after taking natural predecessors. Its square is bounded by the original full sum, giving a harmless factor2. No value of the remainder at0 is assumed to vanish.

The transport uses only the existing independent ordinary SW, ordinary BV and uniform raw Ren/Ghosh inputs of the completed circle-method theorem. No additional deep input or own-paper sieve endpoint is introduced.

Checked declarations: `goldbach_pred_square_sum_bound`, `goldbach_pred_full_square_sum_bound`, `goldbach_sieve_remainders_selected`.

Next obligations

The local-density identities and their multiplicative normalization must still be proved for the actual Euler factors. Then the two-range presieve construction and its levels, dimension bounds, coefficient estimates

and main-term analysis must be completed before either full sieve proposition is awarded source-level credit. The statement map and current paper ledger distinguish these unfinished claims from the checked reductions above.

Section11_Local_Densities.md

Section11: the two local-density lemmas

Both `l:lowerlocaldensity` and `l:upperlocaldensity` are proved for the retained source context. No new external input is used. The selected manuscript is unchanged. The clause-by-clause source review is in `verification/section11-local-density-source-review1221.json`.

The root count is the actual cardinality of the units satisfying the square equation. Consequently zero is excluded from the variable being squared, and rho is zero at the zero residue. Opening the prime Ramanujan sum proves

$$C_p(a) = p\rho_p(a) - (p-1), \qquad \rho_p(a) = \begin{cases} 2, & (a/p) = 1, \\ 0, & (a/p) \neq 1. \end{cases}$$

The normalized character coefficient agrees with the earlier original definition. Its unrestricted factor, when the multiplier is invertible, is

$$1 + G_p = \frac{p(p - 1 - \rho_p(n))}{(p-1)^2}.$$

If the progression fixes its unit variable to b, the factor becomes

$$1 + G_p = \frac{p\rho_p(n - \ell b)}{p-1}.$$

The proof also checks the multiplier-zero case, whose common factor can vanish. The actual unrestricted pair cardinality plus rho equals p-1.

The finite coefficient identity for q dividing ell*k is needed at the small primes. It is proved from reduction of units and their exact normalized fiber mass. Under the source congruence n-ell*b=1 modulo24, this gives the factor8 at2 and3 at3. In particular, the upper modulus12 with its even multiplier is treated correctly at8.

Adjoining one prime p>3 to a coprime progression modulus proves an identity between the original normalized arithmetic factors. The identity multiplies by

$$g(p) = \begin{cases} \rho_p(n-c)/(p - 1 - \rho_p(n)), & p \leq R, \\ 1/(p-1), & p > R, \end{cases}$$

when ell*b=c modulo p. The cutoff is inclusive, including a prime equal to R. Every other prime factor is proved unchanged. Induction over a finite set of distinct primes, followed by the square-free prime-factor product identity, proves the full factorization for d.

For the lower sieve, the actual CRT conditions are b=11 modulo24 and b=1 modulo d, while n=12 modulo24. They give c=1. The base arithmetic factor at modulus24 is proved nonzero, so the paper's original quotient definition is identified with this density. The prime formula is proved for every p>3; the lower sieve's additional restriction p=3 modulo4 is therefore included.

For the upper sieve, the existing source multiplier result supplies ell=2v and v coprime6. The actual conditions vb=5 modulo12 and ell*b+1=0 modulo d imply the required congruence at24 and give c=-1 at every divisor prime. Unit cancellation shows that every representative reduces to the same base class modulo12. The resulting density is

$$g_{n,\ell}(p) = \begin{cases} \rho_p(n)/(p - 1 - \rho_p(n-1)), & p \leq R, \\ 1/(p-1), & p > R. \end{cases}$$

One explicit function omega(d)=d times the product of these prime densities is constructed before all supported square-free d and all representatives of the source CRT classes. Its value at1 and its multiplicativity on coprime arguments are proved. The complete existence and factorization statement is `goldbach_upper_local_density`.

The denominator is positive for p>3. Both candidate densities are nonnegative and at most 2/(p-3), which is below1 for p>=7. At5, a kernel-checked finite calculation gives either rho_5(n)=0, or rho_5(n)=2 and rho_5(n-1)=0. The upper density is therefore at most1/2 at5. This proves its full required range [0,1).

The upper identity never divides by its base arithmetic factor. If a common obstructing local factor is zero, the multiplicative identity still proves equality with zero on both sides. A zero base is not an extra hypothesis or an omitted case.

The paper-level ledger is now19 proved claims,27 complete conditional implications,1 quoted external result and7 open claims, with4 definitions separate. Presieving and the later sieve estimates remain open. The later analytic use of these densities does not retroactively become an input to the local-density proofs.

`Section11_Presieving_Review.md`

Corrected presieving: complete conditional deduction

The corrected full presieving implication is proved in `goldbach_corrected_presieving`, conditional on the independent general one-stage Rosser–Iwaniec fundamental and coefficient inputs. Their exact interfaces are documented in `docs/EXTERNAL_SIEVE_INPUTS.md`. The literal original source lemma remains open until its weaker hypotheses are corrected. Proposed replacement passages are in `Section11_Presieving_Replacements.tex`. They have not been applied to the selected manuscript.

The primary source checked is Yuta Suzuki's The Rosser–Iwaniec sieve, dated14 March2023. Definition8.2 requires the product bound with factor 1+K/log(w), rather than an unrestricted fixed factor K0. Lemma14.7 states the corresponding coefficient estimates with D>=z>=2. Proposition11.8 controls the sieve-function tails. The original official Iwaniec1980 PDF downloads returned403; this review does not claim they were read.

The corrected statement explicitly requires X>=0 and g(1)=1; X=0 is included. Three further points need to be explicit in the manuscript. First, the refined dimension estimate is stronger than a coarse implied-constant estimate. A fixed K0 allows a concentration of local mass at a few large primes, while 1+K/log(w) approaches1 at large w. Consequently the coarse estimate alone is not the hypothesis of the cited coefficient theorem. The refined interval forms of Mertens' theorem are available for the actual outer densities in this application; they must be stated and used.

Second, the preliminary prime set includes p=R. A dimension condition restricted to p<y with y<=R omits that endpoint if R is prime. The proposed formulation bounds the truncated preliminary prime set over all relevant intervals and uses sifting limit R+1. This retains exactly the intended primes p<=R.

Third, D0<D by itself does not place the outer sieve in the range D1>=z, and log(D0)/log(R) tending to infinity by itself does not give the rate needed to absorb arbitrary outer logarithmic losses. The proposed passage states the actual scale R=(log N)^C, the bound R+1<=z<=D1<=N^A, and the intended uniformity. These conditions give preliminary relative errors bounded by a constant times exp(-c(log log N)^2), which dominate every fixed negative power of log N. Applying these scale conditions to the final lower and upper sieve parameters is a separate later obligation.

The checked finite construction does not assume the paper's two-stage conclusion. It starts from independent one-stage lower and upper weight inequalities. For an outer lower coefficient u(d), the preliminary choice is the lower weight when u(d)>=0 and the upper weight when u(d)<0. For an outer upper coefficient, the choices are reversed. Lean proves the resulting pointwise inequalities, then sums them over actual finite sequences. The sequence is represented by a finite set of indices and an arbitrary integer-valued map, so repeated values are counted correctly.

Disjoint prime supports imply coprimality of every preliminary divisor e and outer divisor d. This gives unique decomposition of m=e*d. The flattened coefficient is explicitly the sum over pairs with that product. Lean proves its absolute value is at most1 and that it vanishes for m>=D0*D1. It also proves exact reindexing into the sum over all natural m<D0*D1, using the natural ceiling of the real level. None of these coefficient definitions mentions the density function, the sequence, X or the remainders.

For the main term, let V0 be the preliminary Euler product, and suppose each preliminary coefficient sum differs from V0 by at most epsilon0*V0. The error from either signed selection is proved to be at most

$$\varepsilon_0 V_0 \sum_d |u(d)| g(d).$$

Together with the outer coefficient estimates, this proves explicit finite lower and upper inequalities with the original signed remainders. No positivity assumption on an outer signed weight is introduced. The uniform Euler-product bound and exact rate absorption are now proved and joined to the two independent classical one-stage interfaces in the complete corrected asymptotic deduction. No own-paper endpoint is assumed.

The source-level ledger remains19 proved claims,27 complete conditional implications,1 quoted external result and7 open claims. The presieving supporting theorems do not increase that count by themselves.

The signed outer mass M is proved to satisfy M/V1<=V1^(-2). The refined dimension condition at w=2 and log(z)<=A*log(N) give V1^(-1)<=K2*(log N)^kappa, with K2=(1+K/log 2)*(A/log 2)^kappa. Multiplicativity is needed only on supported square-free integers; its prime-product expression is proved internally.

For t=log(log N), D0=exp(t^3), and preliminary sifting limit exp(C*t)+1, the exact preliminary parameter satisfies s0>=t^2/(C+1) for t>=1. Lean proves this bound, eventual level admissibility and s0 tending to infinity. The explicit common relative error

$$\varepsilon(N) = K_1(\log D_1)^{-\delta} + K_0 e^{-cs_0}\left(K_2(\log N)^{\kappa}\right)^2 \longrightarrow 0$$

is proved uniformly before all admissible densities. For every sufficiently large N, the final coefficients are chosen before g, the finite sequence, X and the remainders. In the paper application they are therefore chosen before n. The main terms contain only the outer functions f_kappa and F_kappa. The natural-absolute-value bridge covers repeated and negative integer sequence values.

The original manuscript is unchanged. The corrected complete conditional variant is recorded separately from the literal-source inventory. Its independent one-stage inputs and classical function normalization remain unproved; the kernel audit verifies the consuming implication. The next mathematical milestone is the actual lower-sieve application.

Section9_Complete.md

Section9 has been reviewed against the actual source, not merely its stale planning map. Its nine numbered statements and the final quantitative exceptional-set theorem all have complete matched formal evidence. The final theorem already followed conditionally at1259; this task removes the remaining elementary arithmetic and seed hypotheses and closes additional source prerequisites.

The primitive sum-of-two-squares criterion is now proved from pinned Mathlib and project algebra. For n=2 mod4, a coprime sum-of-two-squares representation exists exactly when no3 mod4 prime divides n. The proof covers arbitrary prime powers by choosing a conjugate orientation at each split prime, and treats the single factor2 using parity. Consequently l:fromsiftedtop, l:truncationT and c:mastersievereduction are promoted from conditional to proved under their ordinary source hypotheses. The upper arithmetic reduction was already proved. Their actual finite sets, prime-factor multiplicities, closed cutoff and uniform error terms are retained.

The complete source arithmetic exports are goldbach_from_sifted_to_primes_complete, goldbach_truncation_complete, goldbach_section9_master_exact and goldbach_master_sieve_complete. No primitive criterion is a hypothesis. The source assertion that W(alpha) is finite for every alpha>1 is now proved over its full range, including the square-root endpoint singularity; nonnegativity is also proved.

A concrete compactly supported smooth function is constructed with value1 at0 and support inside(-1/8,1/8). The final export goldbach_section9_headline_complete therefore takes only GoldbachSection11Inputs and A>0, and yields the actual real-X exceptional-set estimate. It needs neither a supplied primitive criterion nor a supplied smoothing function. The almost-all statement is also exported as goldbach_section9_exceptional_density_zero.

The circle-method approximation, lower and upper sieve propositions, uniform main-term lower bound and strict numerical gap retain their complete checked conditional scopes. Remaining independent inputs are SW/BV, Ren/Ghosh, the general one-stage sieve and classical sieve normalizations/continuity, the effective multiplicative mean and classical Mertens estimates. None is a paper endpoint. The primitive criterion has been removed from every current claim's external-input list and is explicitly recorded as a proved internal arithmetic lemma.

The Section9 map is reconciled to the actual current nine source statements and their current theorem evidence, replacing the stale1085/1136 planning statuses. The old map is archived. Original manuscript and accepted source hashes remain unchanged. The user is applying the previously supplied Section11 edits; their application is not presumed. No additional Section9 LaTeX replacement was needed. The previously supplied presieving replacement remains the explicitly reviewed target.

The paper ledger now records22 proved under ordinary hypotheses,31 complete conditional implications and1 quoted external theorem among54 reviewed numbered targets, plus4 definitions. This is a statement inventory, not a percentage based on supporting theorem counts. Earlier stronger unnumbered assertions in alternative proof routes retain their separately documented scope; no new completion credit is awarded to them.

Checkpoint1260 separately saved the primitive multiplication proof, and1261 separately saved the complete criterion, general W integral and fixed smooth seed. This checkpoint saves their final Section9 consumption and source reconciliation.

`Section9_Primitive_Two_Squares.md`

The full primitive sum-of-two-squares criterion used in Section9 is now proved unconditionally: for n=2 mod4, n has a coprime sum-of-two-squares representation exactly when no prime3 mod4 divides n. The proof constructs a primitive representation of the odd cofactor using the checked prime-multiplication argument, then doubles it; parity excludes a common factor2. The converse uses Mathlib's already proved obstruction to -1 being a square modulo a3 mod4 prime. No external arithmetic criterion is assumed.

The source's unnumbered assertion that W(alpha) is finite for every alpha>1 is now proved across its full range, with interval integrability of the actual logarithmic kernel. The endpoint square-root singularity is handled by an integrable negative half power; nonnegativity is also proved for the complete range. This extends the earlier special-value formalization at alpha9/8.

A concrete smooth bump with inner radius1/32 and outer radius1/16 is converted to a Schwartz function. Lean verifies value1 at0, nonzero, compact support contained in(-1/8,1/8), and the source support cutoff. Thus the proof will no longer need an externally supplied test function at the final endpoint. No additional source replacement is required for these valid mathematical statements.

This checkpoint saves these prerequisite proofs separately. The next checked export specializes the legacy parameterized Section9 deductions with the proved criterion and fixed seed, and updates the source map. No source claim is promoted before that final statement review. The previously supplied manuscript edits remain in progress; no changed user source is assumed.

`Sharp_Gauss_Asymptotic.md`

Lemma 3.21: sharp bound with an explicit PNT boundary

Checkpoint 10, 22 October 2026. Source label `l:inftyboundsaq`, equation `e:gaussboundknown`. The complete paper-specific deduction is now proved in Lean, conditional on the two standard prime-distribution limits below. The six previously completed numbered results remain unconditional.

Exact external hypotheses

For real y define

$$\theta(y) = \sum_{p \le y} \log p, \qquad W(y) = \sum_{p \le y} p^{-1/2}, \qquad F(y) = \frac{\sqrt{y}}{\log y}.$$

In Lean the sums use `Nat.primesLE (Nat.floor y)`. The proof checks the exact equivalence of membership with p prime and p<=y for the positive cutoffs used. `PrimeAsymptoticInputs` consists of these two hypotheses, for y tending to positive infinity through the real numbers:

$$\theta(y)/y \longrightarrow 1, \qquad W(y)/F(y) \longrightarrow 2.$$

Both limits are explicit fields of a proposition supplied to the conditional theorems. This project does not construct a proof of that proposition. There are no new `axiom` declarations or proof placeholders. A clean transitive axiom audit establishes the validity of the implication; it does not establish the hypotheses.

The second limit is the usual partial-summation consequence of PNT. For clarity about scope, the bridge from PNT to these two limits is also outside the present Lean development. Thus the exact formal dependency is this pair of standard limits, not an imported PNT theorem.

PNT availability and sources

PNT has been formalized in the separate PrimeNumberTheorem+ project. The pinned Mathlib's `docs/100.yaml`, entry 5, links to it, and a targeted source inspection found no PNT asymptotic to import from our pinned Mathlib. The upstream project inspected on 22 October 2026 targets Lean/Mathlib 4.35.0; our existing verified development targets Lean 4.34.1 and Mathlib commit `d13f23b723b8a846827a245b89c10fc7d3f11612`. No upgrade, external import, or external-project axiom audit has been performed. This is an unintegrated dependency, not a claim that PNT has never been formalized. See `verification/pnt-availability.json` for the inspected file hashes.

A published reference is Iwaniec--Kowalski, *Analytic Number Theory*, AMS Colloquium Publications 53, the paper's existing bibliography key `iwaniec`. The classical PNT and its original sources are also recorded in NIST DLMF 27.2, equation 27.2.3. The following elementary bridge explains precisely why the hypotheses are standard PNT consequences; it is a mathematical explanation, not a Lean proof. Writing pi(y) for the prime counting function, partial summation gives

$$\theta(y) = \pi(y)\log y - \int_2^y \frac{\pi(t)}{t}\,dt, \qquad W(y) = \frac{\pi(y)}{\sqrt{y}} + \frac{1}{2}\int_2^y \frac{\pi(t)}{t^{3/2}}\,dt.$$

PNT says pi(y)~y/log y. The first integral is O(y/log y)=o(y), by splitting at sqrt(y) and using pi(t)=O(t/log t). In the second formula the integral is asymptotic to `2*sqrt(y)/log(y)`: replace pi(t) by t/log t above an arbitrarily large fixed lower endpoint, and compare derivatives of the integral with `2*sqrt(y)/log(y)`. Its derivative ratio tends to one. The finite initial interval contributes a bounded constant. These formulas give the two limits.

1. Logarithmic budget, proved without PNT

Let q>=1, S be its prime divisors, and L=log(q). The squarefree product of these prime divisors divides q, so

$$\sum_{p\in S} \log p \le L.$$

`primeFactors_log_budget` proves this using the actual natural prime-factor set, positive products, divisibility, and monotonicity of the real logarithm.

2. Finite threshold inequality, proved without PNT

For every real y>=2,

$$\sum_{p\in S} p^{-1/2} \le W(y) + \frac{L-\theta(y)}{\sqrt{y}\log y}.$$

Put c=1/(sqrt(y)*log(y)) and subtract c*log(p) from each summand. Since sqrt(t)*log(t) increases on t>=1, the difference is nonnegative below y and nonpositive above y. Drop the nonpositive terms, extend the small terms to all primes <=y, and apply the logarithmic budget. The general finite-set comparison and its application are both proved in `PrimeFactorEstimates.lean`. No exact extremizer or prime-factor asymptotic is assumed.

3. Reciprocal and logarithmic corrections, proved without PNT

For L>=2,

$$\sum_{p\in S} p^{-1} \le 1 + \log L + 1/\log 2.$$

For p<=L, enlarge the sum to the harmonic sum through floor(L). For p>L, use `1/p <= (1/L)*(log p/log 2)` and the same logarithmic budget. This proof also covers nonsquarefree q. It deliberately uses a sufficient O(log L) bound; the stronger O(log log L) in the source is unnecessary for 3.21.

Writing A(p)=(1-p^(-1/2))^(-1), the project proves, for every integer p>=2,

$$A(p) \le 4, \qquad \log A(p) \le p^{-1/2} + 4/p.$$

Indeed `log A <= A-1`, and the exact geometric identity is `A-1 = p^(-1/2) + A/p`. The local bound, the identity, and summation over the actual odd prime factors are all checked by Lean.

4. Connect the actual Gauss sums

Checkpoint 09 proved the genuine normalized square-sum estimate

$$|\mathfrak{s}(a,q)| \le q^{-1/2}\, 4 \prod_{p\mid q,\ p>2} A(p) \quad ((a,q)=1).$$

For y>=2 put

$$E(y) = \log 4 + 4(1 + \log y + 1/\log 2), \quad B(y) = W(y) + \frac{y-\theta(y)}{\sqrt{y}\log y} + E(y).$$

The finite proofs give, unconditionally when L>=2,

$$\log\left(4 \prod_{p\mid q,\ p>2} A(p)\right) \le B(L), \qquad |\mathfrak{s}(a,q)| \le q^{-1/2} e^{B(L)}.$$

Under the explicit analytic hypotheses,

$$\frac{B(y)}{F(y)} = \frac{W(y)}{F(y)} + 1 - \frac{\theta(y)}{y} + \frac{E(y)}{F(y)} \longrightarrow 2.$$

The identity is proved for y>1 using sqrt(y)^2=y. The final correction tends to zero by the checked Mathlib limits `(log y)^j/sqrt(y) -> 0`, j=1,2. The fixed constant four at two is therefore absorbed rather than omitted.

5. Full source statement and quantifiers

Define the explicit coefficient error

$$r(q) = B(\log q)/F(\log q) - 2.$$

`gaussAsymptoticError_tendsto` proves r(q)->0 under the two analytic inputs. `principalSquareSum_sharp_error_bound` proves the inequality with exponent `(2+r(q))*F(log q)` without those inputs. The theorem `principalSquareSum_two_add_o_one` combines these into the literal source statement, with one r independent of the integer coefficient a.

`principalSquareSum_sharp_bound_int` also states the equivalent epsilon form: for every epsilon>0 there exists an integer Q such that for every positive q>=Q and every integer a coprime to q,

$$|\mathfrak{s}(a,q)| \le q^{-1/2} \exp\left((2+\varepsilon)\frac{\sqrt{\log q}}{\log\log q}\right).$$

`principalSquareSum_three_bound_int` proves the coefficient-three consequence by choosing epsilon=1. The threshold is existential, as in the source; no effective numerical value is claimed. Modulus zero is excluded explicitly by `NeZero q`. The reciprocal square root is the source's q^(-1/2), and the integer-to-unit equivalence is the same checked one used in checkpoint 09.

There is no new manuscript correction at this checkpoint. No headline theorem or real-character-twisted Gauss bound is claimed proved.

Smooth_Cutoff_and_Dyadic_Arcs.md

An actual smooth cutoff and its rational-arc geometry

The module constructs a real smooth bump centered at zero, with inner radius 1/2 and outer radius 1. Mathlib supplies the constructed function; its properties are proved rather than postulated:

$$\eta \in C^\infty, \quad \eta(-x) = \eta(x), \quad 0 \le \eta \le 1, \quad \eta(x) = 1 \ (|x| \le 1/2), \quad \eta(x) = 0 \ (|x| \ge 1).$$

For the actual dilate $\eta_s(\theta) = \eta(16^s\theta)$, a nonzero value implies $|\theta| < 16^{-s}$. The identity $16^s = (2^s)^4$ gives the major-arc core assertion:

$$q \le R, \quad 2^s \le q, \quad 2R^4 \le N^2, \quad |\theta| \le R/(qN^2) \quad \Longrightarrow \quad \eta_s(\theta) = 1.$$

The proof keeps all constants and proves the required positivity before dividing.

For $s \ge 2$,

$$2\,16^{-s} < (2^{s+1})^{-2}.$$

The preceding rational-separation theorem therefore implies uniqueness of an active rational center whose reduced denominator is at most 2^{s+1}.

Module	New named theorems
SourceArcCutoff.lean	13

Scope and small scales

This proves uniqueness only for s>=2. The first two scales remain for a finite overlap estimate; the strict radius inequality is not silently asserted for them. These functions currently live on real frequencies. The real quadratic integral is not treated as periodic in a noninteger integration variable. The full minor-arc bridge, approximation and high-low operator conclusions remain open.

<!-- checkpoint-verification -->

Verification

All 102 project modules and the root were freshly rebuilt: 3621 jobs pass without warnings/errors. All 813 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 104 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Source_Model_Logarithmic_Rates.md`

Logarithmic rates for the actual source scale

For c,alpha>0 and A>=0, the module first proves the eventual estimate

$$e^{-cx^\alpha} \le 2^A(1+x)^{-A}.$$

It composes the established exponential-versus-power limit with x^alpha, proves the exact power substitution on positive x, and handles the change from x to 1+x. The threshold depends on the fixed parameters.

For the already defined

$$R(N,Q) = \max\{\exp((\log N)^{1/10}), Q^8\},$$

the exact exponent split gives

$$R^{-1/6} = R^{-1/16}R^{-5/48} \le Q^{-1/2}e^{-(5/48)(\log N)^{1/10}}.$$

Consequently, for each fixed A>=0, one natural N0 works for every Q>=1:

$$N \ge N_0 \Longrightarrow R(N,Q)^{-1/6} \le 2^A Q^{-1/2}(1+\log N)^{-A}.$$

No upper bound on Q is needed for this parameter implication; the separate analytic estimates retain their own ranges.

A final general estimate proves that any fixed affine logarithmic factor A+B log R is eventually at most R^epsilon for epsilon>0. In particular,

$$(A + B\log R)R^{-5/12} \le R^{-1/3}$$

eventually. This matches the loss produced by counting finitely many active dyadic model terms.

Module	New named theorems
SourceModelLogarithmicRate.lean	5

Scope

All assertions are proved in Lean from the pinned Mathlib limits; no new analytic input is assumed. These estimates convert an established error rate. They do not themselves establish that rate for the actual prime-square symbol, or complete approximation 6.9 and its remaining minor-arc/periodization obligations.

<!-- checkpoint-verification -->

Verification

All 105 project modules and the root were freshly rebuilt: 3624 jobs pass without warnings/errors. All 828 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 107 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Source_Range_Major_Arc.md`

The uniform source-range major-arc implication

Checkpoint 30. The finite Fourier reduction, actual partial summation, error absorption and source parameter inequalities are now assembled. The major-arc R^-5 implication is proved in the source N,Q range, conditional on the displayed genuine progression-prefix estimate.

Quantified statement

Fix c>0 and put c0=min(c/7,1)/8. There is an integer N0>=1 depending on c alone such that the following holds for every integer N>=N0 and every real Q>=1 satisfying

$$\log Q \le c_0\sqrt{\log N}.$$

Let R=max(exp((log N)^(1/10)),Q^8). For every positive modulus q, complex Dirichlet character chi modulo q, coefficient kappa, beta>0, integer a and real theta, suppose

$$q \le R^{11/10}, \qquad |\theta| \le R/(qN^2).$$

Suppose C>=0 and the actual progression prefix satisfies

$$\left|C_{q,u}(t) - \frac{1}{\phi(q)}\left(t - \kappa\chi(u)\frac{t^\beta}{\beta}\right)\right| \le NC\exp(-c\sqrt{\log N}) \quad (N/2 \le t \le N)$$

for every reduced residue u. Then

$$\left|\widehat{\widetilde{A}}_{N,\Lambda}(a/q+\theta)-\left(\mathfrak{s}(a,q)M_{N,1}(\theta)-\mathfrak{s}_{\chi}(a,q)\kappa M_{N,\beta}(\theta)\right)\right| \leq \frac{4+(2+4\pi)C}{R^5}.$$

`sourceMajorArc_uniform_inverse_fifth` proves exactly this implication. Its N0 is chosen before Q,q,chi,kappa,beta,a,theta and C. Thus the threshold is uniform over the displayed range; the error constant depends only on C. It applies in particular to the source's dyadic N and Q>=2.

Assembly of the proof

`sourceMajorArc_parameter_threshold` composes the proved real-variable eventual parameter conditions with the divergence of the natural numbers in the reals. It chooses a natural threshold at least one. For N>=N0, the actual R therefore satisfies R>=1, log(R)<=log(N), R^5*log(N)<=sqrt(N), and 7*log(R)<=c*sqrt(log(N)).

The fixed-parameter actual-symbol theorem from checkpoint 28 then applies directly. Every integration-by-parts, integrability, finite Gauss-sum and normalization condition has already been discharged. None is reinstated as an assumption in the final theorem.

`sourceMajorArc_uniform_ordinary` gives the separate ordinary statement from a raw prefix estimate around t/phi(q), with no exceptional parameter in its conclusion. Its proof specializes kappa=0 and uses the proved identity for the zero exceptional model. In the exceptional application kappa=1 includes the correction. Data can change between scales N; at each one scale the same data must work throughout [N/2,N].

Exact trust boundary

The raw exponential progression-prefix inequality above is still a theorem hypothesis. This unit does not construct exceptional characters or zeros, prove a Page/Siegel-Walfisz theorem, or assert that an unverified version of a published theorem supplies the hypothesis. Its applicability in the external theorem's own modulus range must be checked separately. The explicit c0 above controls the elementary error absorption.

The major-arc part of Lemma 6.5 is now a verified implication from this raw analytic input in the source range. The independent minor-arc bound has not been established over its full stated range, so full Lemma 6.5 remains open. The next unit handles the exact Ren input and its genuinely proved deduction. Proposition 4.19 and Theorem 1.1 remain later targets; Theorem 1.1 is not counted as formalized.

<!-- checkpoint-verification -->

Verification

All 94 project modules and the root were freshly rebuilt: 3609 jobs pass without warnings/errors. All 760 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 96 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

Strong_Improving_Complete.md

Corollary 4.15: complete strong improving deduction

The source is `c:improvinggeneral`, equation 4.16 (`e:lpimproving`), near line 2431 of the archived `sources/current/Draft5.tex`. All 70 modules and the root received a fresh build: 3467 jobs pass without warnings or errors. All 565 named theorems pass the transitive axiom audit; 72 Lean files pass the source scan.

The paper's abstract high-low assumptions, positivity of both kernels and two genuine uniform l2 bounds imply the full strong improving conclusion:

$$\|A_N f\|_{p'} + \|B_N f\|_{p'} \le D_p N^{1/p'-1/p}\|f\|_p, \qquad \frac{2(s+r)}{2r+s} < p \le 2.$$

The constant is chosen before N, the kernels, the windows and the input. The formal statement works for every positive real N. Both operators are actual Mathlib continuous complex-linear maps between sequence spaces, and they agree with the actual convolution on every finite complex input. The prime-square operators' high-low hypotheses are not established here.

Exact statement and new declarations

`PrimeSquares.highLow_AB_strong_improving` is the paper-facing theorem. It uses P,Q:ENNReal with P.toReal=p and Q.toReal=p/(p-1), and the ordinary Fact instances 1<=P and 1<=Q needed for Banach sequence spaces. `improving_exponents_exist` constructs these parameters for every real 1<p<=2: P=ofReal(p), Q=ofReal(p/(p-1)), with both finite and P<=2<=Q. Thus this parameterization does not restrict the source's real exponent range.

Module	New named theorems	Role
`FiniteOutputDuality.lean`	8	Conjugate algebra, complex test identities, cancellation and genuine output norm
`StrongImproving.lean`	4	Actual finite convolution agreement, strong operator norm and combining two maps
`StrongImprovingTheorem.lean`	2	Real exponent parameters and full abstract Corollary 4.15

No interpolation conclusion, duality assertion or desired strong norm is an external assumption. These are deductions from the already proved finite bilinear estimate and the source's genuine operator hypotheses.

Finite-output duality, including zero coordinates

Let 1<p<=2 and put R=p/(p-1). Then R>=2, (R-1)p=R and 1/R=1-1/p. Given a complex sequence u, define

$$g(x) = |u(x)|^{R-2}u(x).$$

The test has the same complex phase as u. The pairing conjugates the test. At a nonzero coordinate, ordinary positive-base real-power laws give

$$u(x)\overline{g(x)} = |u(x)|^R, \qquad |g(x)|^p = |u(x)|^{(R-1)p} = |u(x)|^R.$$

At a zero coordinate, g(x)=0. This includes R=2, where the real-power convention gives 0^0=1 but its product with u(x)=0 is still zero. Both identities therefore remain valid. The formal proofs split off this case before using positive-base power addition. They retain the complex conjugation and prove the pairing identity as a complex equality.

For a finite output set G let S=sum_(x in G)|u(x)|^R>=0. The identities yield

$$\sum_{x\in G} u(x)\overline{g(x)} = S, \qquad \|g\mathbf{1}_G\|_p = S^{1/p}.$$

Suppose every finite output test satisfies

$$\left|\sum_{x\in G} u(x)\overline{h(x)}\right| \le M\|h\mathbf{1}_G\|_p, \qquad M \ge 0.$$

Testing with g gives S<=M*S^(1/p). If S=0, then S<=M^R immediately. If S>0, divide by its positive 1/p power to get S^(1/R)<=M, then raise to the positive power R. Thus S<=M^R for every finite G, including the empty set. `duality_power_cancel` checks precisely this division, zero case and real-power argument.

`finite_output_power_bound` proves the finite-sum bound, and `lp_norm_le_of_finite_pairing` invokes Mathlib's finite-sum norm criterion to obtain ||u||R<=M for an actual u in lp(R). The proof does not require the untruncated g to belong to lp(p); only its finite truncation is used. No representation theorem for the Banach dual is assumed or needed.

The sharp norm on the actual operator

Fix one positive kernel K, 0<q<p<2, N>0, and constants A,B>=0. Assume

$$|\langle K * \mathbf{1}_F, \mathbf{1}_G\rangle| \le A N^{1-2/q}|F|^{1/q}|G|^{1/q}$$

for all finite sets, and an actual continuous l2 realization with norm at most B. Set

$$a = 1/q - 1/p > 0, \qquad b = 1/p - 1/2 > 0,$$
$$C(A,B,p,q) = 3^{2/p}\left(\frac{A}{1-2^{-a}} + \frac{2^b B}{1-2^{-b}}\right).$$

The already checked theorem `restricted_l2_finite_bilinear_improving` proves, for arbitrary finite F,G and complex f,h,

$$|B_{F,G}(f,h)| \le C(A,B,p,q) N^{1-2/p}\|f\mathbf{1}_F\|_p \|h\mathbf{1}_G\|_p.$$

The existing contractive inclusions lp(p)->lp(2)->lp(R), composed with the l2 realization, give a coarse actual continuous map U:lp(p)->lp(R). This supplies output membership. Its finite-input coordinate identity identifies U(f*1_F) with K*(f*1_F). Applying finite-output duality with

$$M = C(A,B,p,q) N^{1-2/p}\|f\mathbf{1}_F\|_p \ge 0$$

gives the sharper norm bound for every finite input. The previously proved `lp_opNorm_bound_of_finiteInputs` extends it by density with the same constant. This proves `restricted_l2_strong_improving`; its conclusion is a genuine `KernelLpBound`, not a scalar model or a finite-support estimate.

The generic lemmas `kernelLp_realization_single` and `kernelLp_realization_finiteInput` prove that every such realization agrees with finite convolution for arbitrary complex coefficients. Agreement on indicators is sufficient by linearity. The existing uniqueness theorem identifies any two continuous realizations with that agreement.

Both source operators and all exponent cases

Write p0=2(s+r)/(2r+s). The source parameters imply 1<p0<2. For p0<p<2 choose q=(p0+p)/2 before N. The already proved global restricted equation 4.17 supplies one constant A>0 uniform in N and both kernels. Each individual restricted pairing is bounded by their sum.

Apply the strong one-kernel theorem separately, keeping the source's two l2 constants B_A and B_B. Positivity of A_N is an explicit source hypothesis at line 2300; positivity of B_N is already included in `HighLowEndpointInputs`. It is not a new mathematical restriction.

Let C_A=C(A,B_A,p,q) and C_B=C(A,B_B,p,q). Both are nonnegative and independent of N. The checked assembly chooses D=C_A+C_B+1>0 and proves the sum of the two norms is bounded by D*N^(1-2/p)*||f||p for every f. The harmless added one ensures strict positivity even for zero operators. The checked conjugate identity rewrites the exponent as 1/p'-1/p.

For p=2 the coarse realizations already have the genuine l2 bounds; N^(1-2/p)=1. The assembly uses D=B_A+B_B+1 and requires no limiting interpolation argument. The final theorem gives the two actual maps, their finite convolution identities, and the norm estimate for every actual lp input. Uniformity is expressed by the quantifier order.

The proof establishes the global estimate directly from global equation 4.17, so the paper's last partition into intervals is unnecessary in this formal proof. This is an alternative proof of the same conclusion.

Verification and exact experiments

All 70 project modules and the root were freshly compiled with the artifact cache disabled. The 3467-job build has no warnings or errors. Every one of the 565 named project theorems passes the transitive audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 72 Lean files and finds no placeholders or additional axioms. Exact theorem/audit coverage and fresh module/import coverage are checked. No Lean source changed after these checks.

`scripts/check_finite_output_duality.py` independently checks 223988 finite identity instances: 55987 exhaustive vectors of length <=6 over a six-value Gaussian integer alphabet and 10 structured vectors through length 1024, at output exponents 2,4,6,8 and input exponents 2,4/3,6/5,8/7. All pass. Every operation is integral, including independently checked perfect roots; there is no floating point. Empty, zero and nonreal inputs are included.

The diagnostic u=(1,i) at output exponent four gives pairing 2 with the correct test and 0 with a mistakenly conjugated phase. The test suite therefore detects this particular phase error. The experiment covers sampled exponents only. Lean proves the full real exponent statements; the experiment does not independently verify the operator estimate or the prime-square high-low inputs. Exact ranges, digest and arithmetic are recorded in `verification/finite-output-duality-numerical.json`.

No new deep input is used in Corollary 4.15. The two earlier explicit PNT limits for Lemma 3.21 are unchanged and are not used here. The archived manuscript and accepted revision fragments are unchanged. The next work is to establish the prime-square operators' inputs and connect the main applications, with every genuinely external analytic assumption explicit.

`Strong_Interpolation_Foundations.md`

Corollary 4.15: checked interpolation foundations

Current checkpoint 20: the full abstract Corollary 4.15 is complete, including strong interior interpolation and p=2. This document records an earlier stage; see Strong_Improving_Complete.md for the completed proof and current scope.

Checkpoint 18 update: the actual geometric weight bound, exact N scaling, and actual complex block/family estimates are now proved; see `Interpolation_Geometry.md`. The remaining-obligation list below records checkpoint 17. Rank construction, coefficient mass, finite-output duality and final strong assembly still remain open.

Checkpoint 17 proves four supporting modules with 32 named theorems. These complete the operator-realization and density infrastructure, the finite complex-input bridge, and the finite weighted Schur estimate. **The strong interior estimate in Corollary 4.15 is still open.** In particular, the coarse bound below has no improving power of N.

Source correspondence

The source is Corollary 4.15 (`c:improvinggeneral`), near line 2431 of `sources/current/Draft5.tex`. Its equation 4.16 asks for

$$\|A_N f\|_{p'} + \|B_N f\|_{p'} \le C_p N^{1/p'-1/p} \|f\|_p, \qquad \frac{2(s+r)}{2r+s} < p \le 2.$$

Theorem 4.1, the global finite-indicator estimate 4.17, actual restricted weak distribution bounds, and the strong p=2 case were already proved. This checkpoint supplies genuine sequence-space constructions needed for a direct global proof of the remaining interpolation step. It does not invoke the interpolation theorem cited by the paper as an external input.

Module	Named theorems	Checked content
`LpInclusion.lean`	5	Contractive continuous complex-linear inclusions for finite 1<=P<=Q
`FiniteComplexInputs.lean`	11	Finite inputs and norms, actual convolution identity, complex positivity bound
`LpRealizations.lean`	10	Coarse lp realizations, uniqueness, extension of finite norm estimates by density

Module	Named theorems	Checked content
`FiniteSchur.lean`	6	Weighted Cauchy--Schwarz, Schur, Hankel sums, finite lp coefficient bounds

P and Q in the Lean declarations are ENNReal exponents, with their ordinary finite values P.toReal and Q.toReal. The spaces use counting measure on Z, represented by Mathlib's actual `lp`, not a norm formula on an arbitrary function. The Schur and inclusion lemmas also allow other index types.

Contractive inclusions

`lp_inclusion_norm` proves that the canonical inclusion from lp to lq has norm at most one whenever 1<=P<=Q<infinity. Membership comes from `Memℓp.of_exponent_ge`; the new proof establishes the norm inequality.

Writing p=P.toReal and q=Q.toReal, for every finite S it proves

$$\sum_{i\in S}|f_i|^q=\sum_{i\in S}|f_i|^{q-p}|f_i|^p\le\|f\|_p^{q-p}\sum_{i\in S}|f_i|^p\le\|f\|_p^q.$$

The coordinate bound |f_i|<=||f||p and p-summability are already checked Mathlib results. The lp norm criterion converts the finite-sum estimates into the claimed q norm bound. Real-power identities are justified with q>0, including zero coordinates, the zero vector and P=Q. The inclusion is then packaged as `lpInclusion`, an actual continuous complex-linear map. Its operator norm is proved <=1 and its coordinates are unchanged.

Finite complex inputs and positivity

`finiteInputLp F f P` is the actual finite sum

$$\sum_{y\in F}f(y)e_y.$$

It equals f on F and zero outside F. Its exact norm is proved for every positive finite real exponent. Truncating an lp sequence to F does not increase its norm. No support, phase or nonzero coefficient is assumed.

For an l2 operator T agreeing with the kernel on finite indicators, `kernelL2_realization_single` proves T(z e_y)(x)=K(x-y)z by complex linearity. `kernelL2_realization_finiteInput` then proves

$$T(\textstyle\sum_{y\in F}f(y)e_y)(x)=\sum_{y\in F}K(x-y)f(y).$$

Thus arbitrary complex coefficients refer to the same operator as the previous indicator estimates. This is an exact identity for every x.

For a nonnegative real kernel represented in C, define the actual finite sesquilinear pairing

$$B_{F,G}(f,g)=\sum_{x\in G}\sum_{y\in F}K(x-y)f(y)\overline{g(x)}.$$

`finiteKernelPairing_bound_by_indicators` proves

$$|B_{F,G}(f,g)|\le AB\,|\langle T\mathbf{1}_F,\mathbf{1}_G\rangle|$$

when |f(y)|<=A on F and |g(x)|<=B on G, with nonnegative amplitude bounds. Triangle inequality controls the phases. Positivity identifies the sum of absolute kernel coefficients with the original indicator pairing. Empty sets and zero amplitudes are included.

A genuine operator on the required sequence spaces

For 1<=P<=2<=Q<infinity, `lpL2Lift` is the composition

$$\ell^P\hookrightarrow\ell^2\xrightarrow{T}\ell^2\hookrightarrow\ell^Q.$$

Both inclusions are proved contractions, so its norm is <=||T||. It agrees with the explicit finite convolution for every finite complex input. `kernelLpBound_of_l2` packages the coarse bound with its indicator agreement. `kernelLp_realization_unique` proves that two continuous complex-linear maps agreeing on the kernel indicators coincide, using their agreement on coordinate vectors and density.

Taking P=p and Q=p' gives the spaces required by the corollary for 1<p<=2. The generic formal theorem has the explicit exponent inequalities P<=2<=Q. This only supplies a coarse bound. Since 1/p'-1/p<0 for p<2, it cannot by itself provide the required decay as N grows.

`lp_bound_of_finiteInputs` proves a separate density implication. If a continuous lp-to-lq map has norm bound D on all actual finite inputs, it has the same bound on every lp input. The proof uses the norm-convergent net of finite sums from `lp.hasSum_single`, continuity, and preservation of a nonstrict inequality under limits. `lp_opNorm_bound_of_finiteInputs` gives the operator-norm formulation for D>=0. The finite-input estimate is a hypothesis of this generic transfer lemma; its interpolation application remains to be proved, and is not assumed in a final paper theorem.

Weighted Schur, without a support-size loss

For finite S,T, nonnegative weights w(i,j), and any real coefficients c,d, `finite_weighted_schur` proves

$$\sum_{i\in S,j\in T} w_{ij}c_i d_j \le C\Big(\sum_{i\in S} c_i^2\Big)^{1/2}\Big(\sum_{j\in T} d_j^2\Big)^{1/2},$$

provided all row and column sums are <=C, with C>=0. Weighted Cauchy--Schwarz is proved by applying ordinary finite Cauchy--Schwarz to sqrt(w)c and sqrt(w)d. The row and column estimates bound the two weighted energies. Square-root identities complete the bound, including C=0.

`finite_hankel_row_sum_le` proves that a finite row of h(i+j) is bounded by sum h when h is nonnegative and summable. The indexing shift is injective, so no term is counted twice. `finite_hankel_schur` supplies the corresponding matrix estimate. These generic statements require summability and the total-sum bound; those conditions for the proposed interpolation weight are **not yet proved**.

`finite_energy_le_lp` uses the contractive counting-space inclusion to prove the finite l2 coefficient norm is <= its lp norm for 1<=P<=2. `finite_weighted_schur_lp` therefore replaces the two coefficient l2 norms by their lp norms, with the same C. The bound is independent of the number of blocks. No dyadic decomposition is assumed in these statements.

Remaining obligations

The complete strong corollary still needs these connections:

1. Construct a decreasing-magnitude partition of every finite complex input into dyadic rank blocks, proving their cardinalities and lp mass bound, including first, last, empty and tied-value cases.
2. From the two actual indicator estimates, derive the block estimate with its exact N scaling. Prove the proposed geometric weight is summable with a bound uniform in every positive N.
3. Apply the checked complex positivity and Schur estimates to that actual partition and weight. This must yield a genuine finite bilinear lp bound, without an unproved decomposition hypothesis.
4. Prove finite-output lp duality with the correct complex phase. Convert the finite bilinear estimate to the finite-input output norm bound.
5. Apply the checked realization and density lemmas, retain both l2 constants, and assemble the interior range with the existing p=2 case.

Only then can Corollary 4.15 be marked complete. A successful global route would make the paper's interval-localization step unnecessary for this deduction; no such completed global interpolation theorem is claimed yet.

Verification and exact finite probes

All 62 modules and the root receive a fresh build with the artifact cache disabled. All 489 named project theorems are checked by the transitive axiom audit; only propext, Classical.choice and Quot.sound are allowed. There are no new mathematical axioms, proof placeholders or deep analytic inputs. The declaration-discovery scanner now ignores comments and strings, after the audit caught a comment sentence being mistaken for a theorem name.

The deterministic script `scripts/check_interpolation_foundations.py` uses only integers and exact fractions. It records zero failures in 98304 finite complex positive-kernel pairing cases, 160012 vector-pair Schur checks on 259 matrices, and 3410 lp inclusion checks at integer exponents. Empty sets, zero amplitudes, zero weights, signed coefficients and equality cases are included. It also probes the proposed dyadic

weights at 63 parameter choices, including 0<N<1, with 1008 row and 504 Schur checks. Counts are experiment cases; restricted inputs may repeat across cases.

These experiments do not prove the unbounded geometric estimate, sorting, duality or full interpolation. They do not verify the later prime-square operator hypotheses. The general supporting implications above are Lean proofs. Full archived sources and accepted revisions are unchanged. The count of completely proved unconditional numbered results remains nine; Lemma 3.21 retains its earlier explicit PNT hypotheses independently.

`Strong_Interpolation_Plan.md`

Strong interpolation: completed proof route

Checkpoint 20 completes the abstract Corollary 4.15. The former proposed steps below are all proved; none is an external input.

1. Global restricted improving at q, from the actual source high-low and uniform l2 hypotheses: RestrictedImproving.lean.
2. Contractive sequence-space inclusions, actual complex finite inputs, coarse actual realizations and exact-constant density transfer: LpInclusion.lean, FiniteComplexInputs.lean, LpRealizations.lean.
3. Finite Schur and actual uniformly summable geometric weights with exact N scaling: FiniteSchur.lean, InterpolationGeometry.lean, InterpolationBlockBounds.lean.
4. Actual sorted dyadic rank partition, coefficient mass, exact complex regrouping and strong finite bilinear estimate: DyadicRankMass.lean, FiniteMagnitudeBlocks.lean, FiniteBilinearImproving.lean.
5. Complex finite-output norm duality, zero cases and genuine output norm: FiniteOutputDuality.lean.
6. Strong N-dependent norm on actual continuous operators, arbitrary finite complex convolution agreement and density extension: StrongImproving.lean.
7. Both source operators, a constant preceding N and the input, every permitted real exponent and the p=2 endpoint: StrongImprovingTheorem.lean.

The final theorem is PrimeSquares.highLow_AB_strong_improving. See Strong_Improving_Complete.md for the full proof, source correspondence, constants and verification scope. No strong interpolation work remains.

The next task is the actual prime-square operator input bridge, beginning with Proposition 4.19 and its dependencies in Section 6. Those inputs and the main applications are still open. Deep published inputs must remain explicit when not formalized; own-paper deductions are proof obligations.

`Twisted_Gauss_Bound.md`

Lemma 3.24: an unconditional twisted Gauss-sum bound

Checkpoint 11, 22 October 2026. Source label `l:Gcharbound`, equation `e:Gcharbound`, and the definition `e:mathfraksgeneral`.

The complete statement is now proved in Lean, strengthened from real to all complex Dirichlet characters. For every epsilon>0 there is C_epsilon>0 such that for every positive integer q, every Dirichlet character chi modulo q and every integer a coprime to q,

$$|\mathfrak{s}_\chi(a,q)| \le C_\varepsilon q^{-1/2+\varepsilon}.$$

The constant depends only on epsilon, not on q, chi, a, or the conductor. No primitive-character assumption is made. This proof uses no PNT input, unformalized Weil bound, or classification of real characters. The PNT hypotheses in the separate Lemma 3.21 development are unchanged.

1. Source definitions and principal specialization

For a complex Dirichlet character chi modulo q write

$$U_\chi(b) = \sum_{r\in\mathbb{A}_q} \chi(r)e(br^2/q), \qquad \mathfrak{s}_\chi(a,q) = \phi(q)^{-1}U_\chi(-a).$$

`twistedUnitQuadraticGaussSum` and `twistedSquareSum` are exactly these sums, using the actual modular unit group, the standard complex additive character, and Mathlib's complex Dirichlet character. The source

minus sign and totient normalization are retained. The principal-character specialization is proved to equal the previously formalized principal square sum.

Every character value on a unit has norm one, using the checked Mathlib lemma `DirichletCharacter.unit_norm_eq_one`. The normalized twisted sum therefore has norm at most one for every coefficient. This also handles modulus one with its one-element unit group and totient equal to one.

2. Count square fibers

Let

$$K(q) = \#\{u \in \mathbb{A}_q : u^2 = 1\}.$$

The code defines this as the cardinality of the kernel of the squaring homomorphism on the genuine modular unit group. For unit a and any residue b, the fiber of u -> a*u^2 over b has at most K(q) elements. If the fiber is nonempty, fix v in it. Sending u to u/v injects it into the square kernel: unit cancellation gives u^2=v^2, hence (u/v)^2=1. This injection is formalized, including the empty-fiber case, without assuming b is a unit in advance.

3. Orthogonality and square scaling

Reindexing r -> v*r for any unit v gives

$$\chi(v)U_\chi(av^2) = U_\chi(a), \qquad |U_\chi(av^2)| = |U_\chi(a)|.$$

The code proves the exact complex identity before taking norms. No reality condition on chi is needed.

Expanding the norm square and summing over every additive frequency gives the exact finite identity

$$\sum_{b \bmod q} |U_\chi(b)|^2 = q \sum_{\substack{r,s \in \mathbb{A}_q \\ r^2 = s^2}} \chi(r)\overline{\chi(s)}.$$

Indeed the inner frequency sum of e(b*(r^2-s^2)/q) is q if the squares agree and zero otherwise. The additive orthogonality used here was already proved for the genuine standard character in the earlier Cohen development. Taking real parts, each character product contributes at most one, and each r has at most K(q) partners s. Thus the energy E satisfies

$$E := \sum_{b \bmod q} |U_\chi(b)|^2 \le q\phi(q)K(q).$$

The square-scaling orbit has bounded multiplicity by the same fiber lemma. For a unit a, therefore,

$$\phi(q)|U_\chi(a)|^2 = \sum_{v \in \mathbb{A}_q} |U_\chi(av^2)|^2 \le K(q)E \le q\phi(q)K(q)^2.$$

The finite bounded-multiplicity summation inequality is proved separately. Since phi(q)>0, cancellation and the nonnegative square root give

$$|U_\chi(a)| \le K(q)\sqrt{q}, \qquad |\mathfrak{s}_\chi(a,q)| \le K(q)\sqrt{q}/\phi(q).$$

These inequalities are proved for every modulus, character and unit coefficient in the stated domains, not inferred from numerical tests.

4. Modular root counts, including powers of two

At an odd prime power p^j, the unit group is cyclic by the checked Mathlib theorem `ZMod.isCyclic_units_of_prime_pow`. A finite cyclic group has at most two solutions to u^2=1, giving K(p^j)<=2.

At powers of two the proof does not assume cyclicity. Exponents j<=2 are checked by kernel-reduced finite decisions. For j=k+3, the unit 5 modulo 2^(k+3) has order 2^(k+1), by `ZMod.orderOf_five`; its square has order 2^k and belongs to the range of squaring. Hence that range has at least 2^k elements. The entire unit group has 4*2^k elements. The exact finite-group kernel-times-range identity yields K(2^(k+3))<=4. The order, positivity, range membership, group cardinality and cancellation are all checked in Lean.

The unit CRT equivalence induces an explicit bijection between the square kernel at mn and the product of the square kernels at coprime positive m,n. Consequently K(mn)=K(m)K(n). Coprime induction, including q=1, gives

$$K(q) \le 4^{\omega(q)},$$

where omega(q) is the cardinality of the actual finite prime-divisor set. This loose constant is sufficient; the sharper local constant two at odd primes is also proved. The proof uses CRT for square kernels and does not postulate a character decomposition of the original exponential sum.

5. Totient and epsilon absorption

Euler's exact finite product identity and p<=2*(p-1) for every prime p give

$$q \le \phi(q)2^{\omega(q)}.$$

Combining the proved estimates yields the uniform explicit finite majorant

$$|\mathfrak{s}_\chi(a,q)| \le 8^{\omega(q)}q^{-1/2}.$$

The remaining q^epsilon estimate is elementary. More generally, fix B>=1 and epsilon>0, and take

$$N = \lceil \exp(\log B/\varepsilon) \rceil, \qquad A = \exp(N \log B) > 0.$$

There are at most N prime divisors of q not exceeding N. For p>N we have log B<=epsilon*log p. All logarithms of primes are nonnegative, so the already proved squarefree-divisor logarithmic budget gives

$$\omega(q)\log B \le N \log B + \varepsilon \sum_{p|q} \log p \le N \log B + \varepsilon \log q.$$

Exponentiating proves B^omega(q)<=A*q^epsilon, uniformly for every positive q. Applying this with B=8 establishes the full Lemma 3.24. The displayed constant is effective but intentionally very large; no optimization is claimed.

Checked declarations and scope

Component	Lean declaration
Actual twisted sum and principal specialization	`twistedSquareSum`, `twistedSquareSum_principal`
Square-scaling identity	`twistedUnitQuadraticGaussSum_mul_unit_sq`
Square-fiber bound	`unitSquareFiber_card_le`
Exact complex energy identity	`twistedGauss_energy_complex`
Energy upper bound	`twistedGauss_energy_le`
Actual numerator norm bound	`norm_twistedUnitQuadraticGaussSum_le_roots`
Odd and dyadic root counts	`unitSquareRootCount_odd_prime_pow`, `unitSquareRootCount_two_pow`
Exact CRT for square kernels	`unitSquareRootCount_coprime_mul`
Global kernel count	`unitSquareRootCount_le_pow`
Elementary totient estimate	`le_totient_mul_two_pow_primeFactors`

Explicit 8^omega/sqrt(q) bound	`norm_twistedSquareSum_finite_bound`
Full uniform theorem and integer-coefficient form	`twistedSquareSum_uniform_bound`, `twistedSquareSum_uniform_bound_int`

All declarations are directly in namespace `PrimeSquares`. The final integer theorem explicitly states epsilon>0, one positive constant, every nonzero natural modulus q, every complex Dirichlet character and every integer a coprime to q. Nonzero natural moduli are exactly the positive ones intended in the source. The exponent is exactly -1/2+epsilon.

No manuscript correction is needed. This completes the general twisted definition and Lemma 3.24; it does not prove the conductor-sensitive refinements in Lemma 3.27 or any headline theorem.

Independent exact checks

`scripts/check_twisted_gauss.py` constructs every character for each q=1,...,32 from exact local unit-group coordinates, including non-real and imprimitive characters. It uses integer phase counters and reduction modulo cyclotomic polynomials, with no floating point. It checks multiplicativity, the exact energy identity, square scaling, fiber bounds, root-count CRT and integer root/totient inequalities. These finite checks supplement the Lean proofs; they do not establish an unbounded epsilon estimate by experimentation.

Checkpoint 12 continuation: the full conductor-sensitive Lemma 3.27 is now proved by the additional support, induced CRT and majorant arguments in `Conductor_Refinement.md`. This checkpoint 11 exposition describes the preceding uniform bound.

`Uniform_Major_Arc_Parameters.md`

Uniform parameter inequalities for the source major-arc scale

Checkpoint 29. This unit proves the elementary asymptotic parameter conditions needed for the inverse-fifth major-arc bound. It has no prime-distribution hypothesis and introduces no deep analytic input.

Define the actual source scale, for real N,Q, by

$$R(N,Q) = \max\{\exp((\log N)^{1/10}), Q^8\}.$$

The Lean definition is `sourceMajorArcScale`. It is positive everywhere, and at least one when N>=1. In applications N is a positive integer.

Uniformity in Q

For any fixed epsilon>0, real powers satisfy

$$x^{1/10} = o(x^{1/2}) \quad (x \longrightarrow \infty).$$

The supporting theorem `eventually_rpow_le_mul_rpow` proves the general comparison x^a<=epsilon*x^b eventually when a<b. Its proof uses the checked limit of x^(a-b) to zero and division by the positive x^b. Composition with log(N) tending to infinity gives the comparison needed for the first term in R.

If log(Q)<=(epsilon/8)*sqrt(log N), then Q^8<=exp(epsilon*sqrt(log N)). Both terms defining the maximum therefore satisfy the same upper bound. Taking logarithms proves, for all sufficiently large N and every Q>=1,

$$\log Q \le \frac{\epsilon}{8}\sqrt{\log N} \quad \Longrightarrow \quad \log R(N,Q) \le \epsilon\sqrt{\log N}.$$

The threshold depends on epsilon alone, not on Q. This is the quantified statement `eventually_sourceMajorArcScale_log_upper`.

The nonunit budget

For any fixed epsilon>0, eventually

$$\epsilon\sqrt{\log N} \le \frac{\log N}{20}, \qquad \log N \le \exp((\log N)/4).$$

The first follows from the same power comparison; the second follows from Mathlib's proved domination of powers by the exponential. Thus, whenever R>0 and log(R)<=epsilon*sqrt(log N),

$$\log R \le \log N, \qquad R^5 \le \exp((\log N)/4), \qquad R^5 \log N \le \exp((\log N)/2) = \sqrt{N}.$$

`eventually_majorArc_nonunit_conditions` proves both required conditions uniformly for every such R. No unspecified eventual bound is supplied as a hypothesis: the proof establishes its existence from checked limits.

An explicit admissible coefficient

Given any positive decay constant c, take

$$\epsilon = \min\{c/7, 1\}, \qquad c_0 = \epsilon/8 > 0.$$

For all sufficiently large N, simultaneously for every Q>=1 with log(Q)<=c_0*sqrt(log N), the actual source R satisfies

$$R \geq 1, \quad \log R \leq \log N, \quad R^5 \log N \leq \sqrt{N}, \quad 7 \log R \leq c\sqrt{\log N}.$$

This is `eventually_sourceMajorArc_conditions`. These are precisely the elementary inequalities used in checkpoint 28. This choice controls the error absorption; applicability of an external progression theorem in its own modulus range remains a separate condition on that external input. No existence or range of an exceptional zero is asserted here.

The next unit transfers this real-variable eventual statement to integer N and connects it to the actual ordinary and exceptional major-arc bounds. Full Lemma 6.5 and Theorem 1.1 remain open.

<!-- checkpoint-verification -->

Verification

All 93 project modules and the root were freshly rebuilt: 3608 jobs pass without warnings/errors. All 757 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 95 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. No new deep analytic input or own-paper lemma is assumed.

`Weighted_Upper_Main_Term_Complete.md`

Weighted upper main term: complete conditional proof

This file concerns the source lemma `l:wumatomakisum`, with alpha=9/8. The checked endpoint is `goldbach_weighted_upper_main_term_complete`. For every A>0, every fixed C>=A+24, and every eta>0, it gives one threshold in N such that the source inequality holds for every n=12 modulo24 with N^2(log N)^(-A)<=n<N^2. Its coefficient is c_alpha W(alpha)+eta, where c_alpha=16 exp(-gamma/2)/sqrt(pi alpha). This is the uniform epsilon formulation of the source o(1).

The theorem uses the actual finite multiplier set, source Euler products, smoothed singular integrals, and lower main term. No weighted-prime sum, error-absorption conclusion, or Goldbach main-term comparison is an independent hypothesis.

Independent inputs

Four general interfaces remain explicit theorem parameters: `ClassicalHalfMeanValueInput`, `ClassicalPrimeLogMertens`, `ClassicalPrimeMertensRatios`, and the existing `GoldbachClassicalIntervalMertens`. The first is the nonnegative strongly multiplicative upper corollary of the corrected Tenenbaum effective mean theorem, with uniform constants and its prime-balance condition stated explicitly. The others contain ordinary fixed-progression Mertens estimates. Their exact scope and the external corollary reductions are

recorded in `docs/EXTERNAL_WEIGHTED_MEAN_INPUTS.md`. They are hypotheses, not new Lean axioms. Their truth is not asserted by this project.

Arithmetic normalization

The source multiplier ell=2up has a unique pair (u,p): the primes dividing u are 1 modulo4 and p is 3 modulo4. Lean proves the finite image identity and uniqueness, including the lower prime endpoint p=z. The geometry gives R<z_ell, u<z_ell<p, and N^2/ell>=2 for all source pairs once R<N^(2/9).

For every odd prime p>3, the joint factor U_p is positive. The associated strongly multiplicative weight h_R has nonnegative prime values at most6. The small-prime cancellation identities are proved even when an individual arithmetic factor vanishes. They yield the exact normalizations

$$X_n\Theta_n(z) = 3C_R(n)H_{1,R}(n)V_3(R,z),$$

and

$$X_n(2up)\Theta_{n,2up}(z_{2up}) = 6B_R(n)\frac{h_R(u)}{2up}H_{2up,R}(n-1)V_0(R,z_{2up}).$$

Here V_3 and V_0 are the actual finite outer Euler products. The positive factors satisfy B_R<=C_R. These are equalities in the original definitions, not asymptotic replacements.

The varying multiplicative weight

Above R the prime values of h_R equal the fixed 1 modulo4 baseline (p-1)/(p-2). The finite perturbation below R and the classical logarithmic prime sums give, uniformly in n and y>=R,

$$\left|\sum_{p\le y}(h_R(p)-1/2)\frac{\log p}{p}\right| \le 6\log R + 10K_0.$$

The application of the independent effective mean theorem is proved from this bound. The finite Euler product is exactly C_R/B_R times an ordinary 1 modulo4 product. Thus, with kappa=exp(-gamma/2)/sqrt(pi), the ordinary partial sum is at most

$$(\kappa + K\varepsilon^{\delta})(1+K_1/\log R)\frac{C_R(n)}{B_R(n)}\frac{x}{\sqrt{\log R\log x}}$$

under the explicit scale and prime-balance budgets. Constants K,delta precede R,n,x,epsilon. At R=(log N)^C and a=exp(sqrt(log N)), Lean proves every budget eventually, uniformly in n.

The small denominators do not require this sharp mean estimate. A coarser instance applies beyond R^D for a fixed D>1. Below that scale a finite Euler-product bound applies; above it a checked Abel identity applies. Together they give

$$\sum_{u\le a}\frac{h_R(u)}{u} \le \frac{C_R(n)}{B_R(n)}\left(P(\log R)^6 + A'\frac{1+\log a}{\log R}\right),$$

with constants independent of R,n,a. After multiplication by the prime reciprocal and kernel bounds this range is negligible on the required scale.

The double weighted sum and W

Two finite Abel estimates are proved with their derivatives, signs, integrability, floor conventions, and boundary terms. The denominator summation is bounded using the preceding mean. Finite variable-interval integration interchanges its order with the prime sum. The prime sum uses the 3 modulo4 logarithmic Mertens estimate. The possible prime p=z contributes at most 1/(z(log z)^2); its remaining error is at most 2(2K_0+1)/(log z)^3.

At D=2 log N, the logarithmic variables r=log(2u)/D and v=log p/D give the actual source region. The two changes of variables are checked, and

$$\int_0^{1/9}\frac{dr}{\sqrt{r}}\int_{4/9}^{(1-r)/2}\frac{dv}{v(1-r-v)^2} = 8\sqrt{2}\,\mathcal{W}(9/8).$$

The endpoint at r=0 is integrable. Replacing log u by log(2u) costs at most sqrt(1+log2/log a), which tends to one. The small-denominator, prime, and Abel boundary coefficients all tend to zero. Choosing epsilon arbitrarily small therefore proves, uniformly in n, the sharp fixed kernel bound with coefficient kappa W(9/8)+eta. A checked logarithmic-loss argument proves the same bound for every m in the entire retained interval N^2(log N)^(-A_1)<=m<=N^2.

Integration, smoothing, and relative errors

The finite sum of original Archimedean integrals is interchanged exactly with integration. On the retained region the logarithmic kernel bound is compared directly with the defining integrand of H_1(n): log(n-y^2)<=2 log N. No assertion about an unrestricted real power of log m near m=0, or a relative shift H_1(n-1)/H_1(n), is needed.

The discarded set has measure at most 2T/sqrt(n). The actual reciprocal mass over pairs is at most M(log N)^7. The already proved singular-integral smoothing bound is uniform in the multiplier, so its total error is also controlled by that mass. The lower bound for H_1(n) on the retained n range is proved internally.

For A_1=A+14 and C>=A+24, both total errors are bounded relative to the common positive quantity

$$S = C_R(n) H_1(n) \sqrt{\log R / \log N}.$$

The discarded-region contribution is at most 768 M/(log2)^3^(-3) S, and the total smoothing contribution at most 48 M K (log N)^(-2) S. The lower smoothing error is at most 8K_s/log N times H_1(n). All three coefficients tend to zero with thresholds independent of n.

Final comparison

The full Mertens ratio and log z_ell=one-quarter log(N^2/ell) give the upper coefficient 48(kappa W+o(1)) multiplying S. The exact lower normalization and half Mertens ratio give the lower coefficient 3 sqrt(9/8)+o(1). The identity 3 sqrt(alpha)c_alpha=48 kappa is checked. A positive-tolerance continuity argument concludes the original uniform source inequality.

The theorem statement needs no replacement. Two proof passages are supplied separately in `docs/WEIGHTED_UPPER_MAIN_TERM_REPLACEMENTS.tex`: the non-strict lower endpoint p>=z, and Step6 with its retained cutoff and direct H_1(n) comparison. The selected manuscript is unchanged.

Checkpoint notes 42-116

Checkpoint_42_UniformMajorArcBudget.md

Checkpoint 42: Uniform arithmetic thresholds for the major-arc model error

The finite major-arc budget is the actual sum of the prefix error and the tail from all other model terms:

$$B_C(R) = \frac{4 + (2 + 4\pi)C}{R^5} + \left(5 + \frac{\log R}{\log 2}\right) \frac{4C_G}{\pi} R^{-5/12}.$$

The new proof gives a single natural-number threshold for every real Q. First the exponential part of R=max(exp((log N)^(1/10)),Q^8) tends to infinity independently of Q. This transfers the already proved eventual R^(-1/6) budget estimate uniformly to this scale. Joining this threshold with the proved logarithmic absorption gives, for every fixed C>=0 and A>=0, one N0 such that for all N>=N0 and all Q>=1,

$$B_C(R(N, Q)) \le 2^A Q^{-1/2} (1 + \log N)^{-A}.$$

The N0 may depend on C and A; it does not depend on Q. This is a genuine quantifier strengthening needed for the source approximation. No distribution theorem, minor-arc estimate or own-paper lemma is assumed by these three results. Applying this budget to the actual finite model still requires the major-arc hypotheses and the displayed raw progression-prefix estimate from checkpoint 41.

Verification

All 109 project modules and the root were freshly rebuilt: 3628 jobs pass without warnings/errors. All 848 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 111 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

Checkpoint_43_MajorArcBudgetGeometry.md

Checkpoint 43: Source parameter budgets imply both major-arc geometric conditions

The prefix-error parameter budget also supplies the rational-arc geometry needed for the actual model comparison. For N>2, R>=1 and log N>=1, the inequality R^5 log N<=sqrt N implies both 2R^3<N^2 and 2R^4<=N^2. The proof compares R^3 and R^4 to R^5, and sqrt N to N; no asymptotic constant is hidden.

Combining this elementary deduction with the already checked source parameter threshold gives one natural-number N0, independent of Q, for both geometric conditions throughout the authorized source range log Q <= min(c/7,1)*sqrt(log N)/8. These conditions establish disjoint major arcs and force the actual smooth cutoff to equal one on the chosen major arc. The raw progression-prefix estimate and full minor-arc estimate are not established by this unit.

`Checkpoint_44_UniformFiniteMajorArcError.md`

Checkpoint 44: Uniform logarithmic major-arc approximation for the actual finite model

The actual finite model error now has the full major-arc logarithmic rate with a single threshold independent of Q, the finite set of canonical rational centers, the chosen major arc and the exceptional character data. For fixed C>=0, c>0 and A>=0, and the established source range for Q, the theorem concludes

$$\|\widehat{A}_N(\xi) - V_{N,\Gamma}(\xi)\| \le 2^A Q^{-1/2}(1+\log N)^{-A}.$$

The hypotheses are explicit: N sufficiently large; Q>=1 in its source range; canonical centers with denominator at most R(N,Q); coefficient norms at most one; beta in (0,1]; a chosen center in the finite set with the required major-arc width; and the actual von-Mangoldt progression-prefix estimate throughout the positive annulus with the same exceptional data. The proof joins the source parameter, geometric and error-budget thresholds, applies the checked prefix-to-model estimate, then absorbs the counted tail. No minor-arc estimate or existence of exceptional data is assumed implicitly. This is the major-arc branch for the finite real-frequency model; the source's global approximation is still open.

`Checkpoint_45_AnnularFrequencyContinuity.md`

Checkpoint 45: Continuity in frequency of the genuine annular oscillatory integral

The genuine normalized annular oscillatory integral is continuous as a function of the real frequency, for every positive natural arithmetic length N and every real exponent beta. This proves regularity of the actual integral; it is not an extra hypothesis on a model function.

The proof first establishes joint continuity of the quadratic phase in frequency and integration variable. To apply compact parametric integration for arbitrary beta, the power density is continuously extended by replacing t with max(t,N/2). This extension is strictly positive and equals the original density throughout the integration annulus. The compact-interval integral is then identified with the original half-open integral, whose endpoint difference has measure zero, and the exact factor 1/N is preserved. This regularity will support continuous circle multipliers after periodization. It does not supply any prime-distribution estimate.

`Checkpoint_46_LocalizedModelContinuity.md`

Checkpoint 46: Continuity of the genuine localized Gauss models

The actual Gauss model and its localized smooth-cutoff version are continuous in real frequency. Both statements hold for arbitrary character, coefficient and exponent data at every positive arithmetic length, without any distribution assumptions. Their proofs combine the genuine annular integral regularity with the actual smooth cutoff. This discharges the continuity requirement for the forthcoming quotient construction, rather than assuming continuity of the manuscript model.

`Checkpoint_47_CompactPeriodWindow.md`

Checkpoint 47: The finite periodization window and its endpoint compatibility

For a continuous real symbol supported inside [-1,1], periodization on the centered fundamental interval uses exactly the three translates f(x-1)+f(x)+f(x+1). The new proofs establish continuity, exact equality of the values at -1/2 and 1/2, and the uniform bound 3B when the original symbol has norm at most B. The endpoint identity includes the possible overlap at the largest cutoff scale; it is not assumed that only one translate contributes. These elementary analytic facts prepare a valid continuous circle symbol. They do not assert prime-distribution estimates.

`Checkpoint_48_CompactCircleLift.md`

Checkpoint 48: A continuous circle symbol from a compact real-frequency symbol

A real continuous symbol supported in [-1,1] now gives a genuine continuous function on the unit circle. The quotient uses the centered half-open fundamental interval and the three-translate window. Continuity follows from the proved endpoint compatibility; it is not obtained by treating a nonperiodic real function as periodic. The theorem identifies its value with the finite window on [-1/2,1/2) and proves a uniform norm bound 3B. These statements handle the largest cutoff scale, where neighboring translates can overlap.

`Checkpoint_49_CompactPeriodSum.md`

Checkpoint 49: Exact integer-sum interpretation of compact periodization

The integer-translate sum of a real symbol is proved one-periodic by an exact reindexing of the integer summation. For a symbol vanishing whenever |x|>=1, the infinite sum on the centered fundamental interval is proved equal to the three-term window. Every omitted integer translate is shown to vanish; no convergence or truncation error is assumed. This identifies the finite construction with genuine periodization, including both endpoints.

`Checkpoint_50_CompactCircleCore.md`

Checkpoint 50: Exact local agreement for narrow periodized symbols

When a real symbol vanishes already for |x|>=1/2, the two neighboring translates in the periodization window vanish throughout the closed centered interval. The resulting continuous circle symbol therefore agrees exactly with the original real symbol on [-1/2,1/2). This proves the absence of alias terms for sufficiently narrow cutoffs; the largest cutoff remains covered by the earlier three-translate formula. No periodicity of the original oscillatory integral is asserted.

`Checkpoint_52_CompactCirclePeriodization.md`

Checkpoint 52: Global identification with genuine integer periodization

The continuous quotient construction is identified globally with the lift of the genuine integer-translate sum. The proof chooses the unique representative in the centered half-open interval, applies the proved finite-window identity there, and uses the quotient's exact representative identity. Consequently, for every real x, the circle symbol at x modulo one equals the infinite sum of f(x+k) over all integer k. This global equality removes the restriction to one fundamental interval and proves that the construction is actual periodization, not an arbitrary endpoint-compatible extension.

`Checkpoint_55_CircleRationalModelNorm.md`

Checkpoint 55: Uniform Gauss decay survives actual circle periodization

The genuine centered rational model has the previously proved Gauss decay C_G q^(-5/12), uniformly in frequency, for N>=2, beta in [0,1] and exceptional coefficient of norm at most one. Its actual periodized circle term has bound 3 C_G q^(-5/12). The factor three accounts for the largest cutoff's possible aliases and is justified by the proved periodization estimate. C_G is the single unconditional constant already extracted from the formalized quadratic Gauss estimates; no prime-distribution input is added.

`Checkpoint_56_FiniteCircleModel.md`

Checkpoint 56: The genuine global finite circle model and its uniform Gauss bound

A global continuous circle model is now defined for any explicit finite set of rational centers, using the genuine periodized Gauss terms. Its evaluation at every real frequency is proved to equal the finite sum of actual integer-periodized centered models. A uniform pointwise bound is proved by summing the unconditional denominator-dependent Gauss bounds, with the alias factor three included. The error is defined as the difference between the genuine von-Mangoldt annular symbol and this continuous model. This establishes a valid global finite model; identifying the manuscript's exact center set and proving its uniform approximation still require further work.

`Checkpoint_58_UniformFourierKernel.md`

Checkpoint 58: Uniform inverse-kernel and finite-input convolution estimates

Every continuous circle symbol with a uniform pointwise bound B has an inverse Fourier kernel bounded by B at every integer. The proof uses the actual Fourier coefficient integral, the unit norm of the Fourier

character and the normalized Haar mass one. This gives an explicit finite-input convolution bound B times the sum of input magnitudes, valid without positivity or compact spatial support. These facts supply the basic l1-to-linfinity kernel estimate needed for low operators; the source's stronger low estimate is not claimed.

Verification

All 126 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3645-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 882 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 128 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains

two earlier explicit PNT limits; its external bridge is not integrated or used here. The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

`Checkpoint_60_KernelL1Value.md`

Checkpoint 60: The bounded convolution sequence and its additive structure

The absolutely convergent convolution of a bounded kernel and an arbitrary l1 input is packaged as a genuine linfinity sequence. Its norm is proved at most B times the input norm, and addition of inputs is proved compatible with the sequence-valued construction using justified summation of the two absolutely convergent series. These results prepare the actual bounded linear low operator required by the abstract high-low framework.

The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

`Checkpoint_61_KernelL1Operator.md`

Checkpoint 61: A genuine bounded linear l1-to-linfinity convolution operator

Bounded-kernel convolution is now a genuine complex continuous linear map from integer l1 to integer linfinity. Complex linearity is proved directly from the convergent series, the application formula is the actual convolution sum, and its operator norm is at most the kernel bound B. The construction does not assume positivity or finite kernel support, so it applies to smooth Fourier-cutoff inverse kernels whose spatial support need not be compact.

Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

`Checkpoint_62_KernelL1FiniteAgreement.md`

Checkpoint 62: Exact agreement of infinite convolution with finite and indicator inputs

The newly constructed infinite l1 convolution operator is proved to agree exactly with the existing finite convolution on every finite complex input. Its indicator-input specialization agrees with indicatorConvolution. The proof removes all terms outside the finite support by an exact summation identity; it does not approximate the infinite sum. These identifications connect the new all-input low operator to the already formalized restricted high-low framework.

`Checkpoint_63_FourierL1Operator.md`

Checkpoint 63: Compatible l1 and l2 realizations of continuous circle multipliers

Every continuous circle multiplier now has a genuine l1-to-linfinity convolution realization using its actual inverse Fourier kernel. The operator norm is at most the symbol sup norm. On every finite complex input its values agree exactly with the independently constructed l2 Fourier multiplier, with the same negative-phase convention. This compatibility is needed when combining l1 low bounds and l2 high bounds for the same averaging operator.

`Checkpoint_64_KernelSensitiveFourierL1.md`

Checkpoint 64: Operator estimates from sharper inverse-kernel bounds

The l1-to-linfinity operator is bounded by any valid pointwise bound on its inverse kernel, even when that bound is smaller than the symbol sup norm used to construct the operator. Both the all-input norm estimate and the operator-norm estimate are proved. This distinction is useful for the source's low term, where arithmetic cancellation in the inverse kernel must provide a sharper bound than the immediate symbol estimate. No such arithmetic cancellation is assumed or claimed in this checkpoint.

`Checkpoint_65_FourierKernelAlgebra.md`

Checkpoint 65: Pointwise linearity of actual inverse Fourier kernels

Inverse Fourier kernels are proved compatible with addition, complex scalar multiplication and subtraction. The proof uses the actual continuous-map-to-L2 map and the inverse Fourier isometry, so the identities hold pointwise at every integer, not merely almost everywhere in frequency. These algebraic identities are required to turn a symbol decomposition into an exact spatial-kernel decomposition.

All 143 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3662-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 916 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 145 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

`Checkpoint_77_CenteredHighSymbol.md`

Checkpoint 77: The compact centered high symbol and exact total-model identity

The centered high symbol is constructed as the genuine localized total model minus the compact low symbol. It is continuous as a continuous-map difference, its compact support is proved, and low plus high equals the genuine centered Gauss model exactly. Source identification remains separate from this unconditional candidate decomposition: the extra low cutoff must be shown redundant under the appropriate width conditions.

Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

Checkpoint_78_CircleLowTerm.md

Checkpoint 78: The actual periodized low term on the unit circle

The compact centered low term now gives a genuine continuous unit-circle symbol translated by its rational center. Its value at every real frequency is proved equal to the actual integer periodization of the centered low symbol. The construction has no implicit periodicity or convergence assumption. Identifying the centered compactification with the paper's low expression requires the explicit containment conditions recorded separately.

Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

Checkpoint_79_CircleHighTerm.md

Checkpoint 79: The periodized high term and exact low-plus-high identity

The compact high term is likewise periodized into a genuine continuous circle symbol. Its global integer-sum evaluation is proved, and the periodized low and high terms sum exactly to the previously constructed rational Gauss-model circle term. The proof uses the actual quotient representative and finite window, so it handles alias terms rather than dropping them.

`Checkpoint_80_FiniteCircleHighLow.md`

Checkpoint 80: Global finite low and high symbols with the actual annular error

Finite sums of the genuine low and high circle terms define continuous global finite low and high model symbols. Their sum equals the actual finite circle Gauss model. Adding the defined actual error gives exactly the annular von-Mangoldt averaging symbol, as an equality of continuous maps on the circle. This provides an unconditional candidate decomposition for the explicit finite center set; it does not supply the missing source-specific norm estimates or full minor-arc approximation.

`Checkpoint_82_CircleHighLowOperators.md`

Checkpoint 82: Genuine low l1 and high l2 operators with finite convolution formulas

The low circle symbol defines an actual bounded linear operator from integer l1 into linfinity; the high symbol defines an actual l2 Fourier multiplier. On every finite complex input both operators are proved to equal convolution with their respective genuine inverse kernels. This aligns the two different input norms with a common spatial decomposition and avoids treating formal symbols as already-defined convolution operators.

`Checkpoint_85_OrdinaryLowContainment.md`

Checkpoint 85: The extra broad cutoff is redundant for the ordinary narrow term

For a positive narrow parameter Q with Q<=R, rational denominator q<=R and 2R^4<=N^2, multiplying the exact ordinary narrow cutoff by the broad dyadic cutoff leaves it unchanged. The proof applies the real cutoff-containment theorem with the actual log2(q) index and transports the identity to complex values. This justifies redundancy of the extra broad cutoff for the ordinary part in this range.

`Checkpoint_90_FiniteMaximalEnvelopeBound.md`

Checkpoint 90: Finite-family l2 maximal control through the explicit envelope

The finite l2 envelope has norm at most the sum of the individual operator bounds times the input norm. Every nonnegative pointwise function dominated by this envelope is proved to belong to real l2 with the same bound. In particular, this supplies the finite-family maximal bound once a pointwise maximum is dominated by the envelope. The bound depends on the sum of scale bounds; proving the source's uniform infinite-family or multifrequency maximal estimate remains open.

`Checkpoint_91_CircleHighLowAssembly.md`

Checkpoint 91: Actual high-low assembly and completion of the fifty-checkpoint batch

The actual finite circle construction is now connected to the previously formalized operator high-low framework. An explicit uniform bound on the genuine low inverse kernel and an explicit uniform symbol bound on the sum of high and error imply OperatorHighLowBound for the actual annular von-Mangoldt square kernel. The spatial normalization is N^2, where N is the arithmetic length. The low witness is the genuine l1-to-linfinity convolution operator; the high witness is the actual l2 Fourier multiplier of high plus error. Their agreement on indicator inputs is derived from the exact finite-input decomposition.

This is an assembly theorem with its two analytic inputs displayed. Those source-specific inputs are NOT proved by this theorem, are NOT registered as axioms, and are NOT evidence that Proposition 4.19 or Theorem 1.1 is complete. The remaining global minor-arc deduction, source center-set/parameter identification and sharp analytic low/high/maximal estimates are documented explicitly. The partial formalization has no newly added analytic axioms or own-paper lemma assumptions hidden in a completed numbered result.

This checkpoint ends the requested batch of 50 separately saved checkpoints, numbered 42 through 91. The combined Batch_42_91_Report.md gives the complete ledger, verification method and outstanding obligations. The entire project is freshly rebuilt again here, then every named theorem's complete transitive axiom set, source constraints, frozen manuscript hashes and ZIP entries are checked before saving.

The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

`Checkpoint_92_CanonicalRationalCenters.md`

Checkpoint 92: The exact finite set of reduced canonical rational centers

A concrete finite set of canonical rational centers is defined, and its membership is proved exactly equivalent to 0<=r<1 and den(r)<=M. The construction enumerates a finite numerator-denominator box and filters by this exact predicate; it is not a sample or an incomplete denominator list. The normalized denominator is used, so fractions with different unreduced presentations do not introduce duplicate centers.

The proofs include the exact numerator and denominator ranges, monotonicity in M, the empty M=0 case, inclusion of the denominator-one center zero exactly when M>=1, and a finite cardinality bound. For a real cutoff R>=0, membership is proved equivalent to canonicality and den(r)<=R by using floor(R). This supplies the precise finite rational index set required by the model rather than leaving an arbitrary finite set as the only interface.

This identifies the reduced canonical rational index predicate. The character/coefficient data and complete summation correspondence are not silently supplied by this construction. No prime-distribution estimate, analytical approximation or deep input is used in these finite arithmetic proofs.

All 947 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 161 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

`Checkpoint_93_WrappedRationalArcGeometry.md`

Checkpoint 93: Rational arc geometry with every integer lift

This checkpoint proves rational-arc geometry on the circle while retaining every integer lift. Two different canonical center/lift pairs with denominators at most D are separated by at least 1/D^2. The proof treats distinct reduced rationals and distinct lifts of the same rational separately. Consequently two arcs of common radius delta with 2*delta<1/D^2 cannot meet unless both their centers and integer lifts agree.

For the manuscript's major-arc widths R/(q*N^2), the condition 2*R^3<N^2 gives uniqueness of the center/lift pair. If a frequency is on the major arc of r0, every distinct center or nonzero integer shift is strictly outside its own major arc. In particular, shifted copies of r0 itself are not omitted. The same argument proves uniqueness for the actual dyadic cutoff at scales s>=2. The earlier low-scale overlap bound remains applicable at the smaller scales; no uniqueness claim is made there.

The exact quotient identity says that adding any integer to a real representative gives the same point of PrimeCircle. Together these results cover the wrap across zero and one without assuming that the real-variable oscillatory integral is periodic. The proofs use only finite rational arithmetic, inequalities and the circle quotient; no progression estimate or minor-arc conclusion is assumed.

Checkpoint_94_PeriodizedModelTails.md

Checkpoint 94: Exact periodization and logarithmic circle-model tails

The genuine periodization is reduced exactly to the five integer shifts -2,-1,0,1,2 for every canonical rational center and every real representative xi in [-1,2]. The centered cutoff model vanishes at distance at least one; this proves that all omitted shifts are zero, including the boundary cases. Summing over the rational centers and interchanging the finite sums gives the exact same representation for the actual continuous circle model.

If a representative is outside every small major arc at each of those five shifts, the actual circle model has norm at most

```
T_circle(R) = 5\*(5+log(R)/log(2))\*(4\*C_G/pi)\*R^(-5/12),
```

where C_G is the positive constant chosen from the previously proved, unconditional ordinary/exceptional Gauss-model bounds. This is a logarithmic tail estimate, rather than the much larger sum of absolute coefficient bounds over all denominators. All cutoffs and actual integral models retain their existing definitions.

A common approximation budget is defined by

```
B(C,R) = (4+(2+4\*pi)\*C)/R^5 + C_G\*R^(-5/12) + T_circle(R).
```

Lean proves that T_circle(R)<=R^(-1/3) eventually and B(C,R)<=R^(-1/6) eventually for every fixed C>=0. Substituting the actual source scale R=max(exp((log N)^(1/10)),Q^8) gives, for every A>=0, a threshold in N independent of Q>=1 with B(C,R)<=2^A*Q^(-1/2)*(1+log N)^(-A).

This checkpoint bounds the model and its explicit error budget. It does not prove that the prime-square multiplier is close to that model at all frequencies. No distribution hypothesis is consumed by these statements. The actual approximation branches are treated in the subsequent checkpoints; the full-range minor-arc problem remains open.

Checkpoint_95_PeriodizedMajorArcError.md

Checkpoint 95: Conditional major-arc approximation for the genuine circle model

This checkpoint transfers the progression-prefix major-arc estimate to the actual continuous circle error. It does not replace the circle model by its unperiodized real-variable counterpart. The old real-model error is combined with four additional integer shifts, obtained from the exact five-shift identity proved in checkpoint 94.

If xi is on the major arc of a canonical center r0 with denominator at most R, the separation condition 2*R^3<N^2 shows that every nonzero shift is outside every center's own major arc, including the shifted copies of r0. Their combined norm is at most four real-model tail budgets. The zero-shift error already contributes at most the inverse-fifth progression error plus one such tail. Thus the actual circle error is bounded by the common circleApproxBudget(C,R). The proof also establishes that the chosen lifted representative lies in [-1,2], so the finite-shift formula applies without an extra hypothesis.

The explicit inputs include N>=2, R>=1, 0<beta<=1, coefficient norms at most one, 2*R^3<N^2, 2*R^4<=N^2, log R<=log N, R^5*log N<=sqrt N and 7*log R<=c*sqrt(log N). The sole unproved distribution input is the displayed inequality for progressionMangoldtPrefix on the whole positive real interval [N/2,N], with error N*C*exp(-c*sqrt(log N)); the same character/coefficient/beta data must work throughout this interval. No approximation conclusion from the manuscript is assumed.

For the exact sourceRationalCenters(R) with R=sourceMajorArcScale(N,Q), the uniform theorem supplies one N threshold, independent of Q and the permitted exceptional data, giving

```
norm(circle error) <= 2^A\*Q^(-1/2)\*(1+log N)^(-A).
```

Here C>=0, c>0, A>=0, Q>=1 and log Q <= (min(c/7,1)/8)*sqrt(log N). Canonicality and denominator bounds come from the exact membership theorem of checkpoint 92. Arcs crossing the circle boundary are handled by choosing their integer-shifted real representative; checkpoint 93 proves that its circle point is unchanged.

This completes this conditional major-arc branch for the actual periodized model. It is not the global approximation Lemma 6.9: the intermediate and larger denominator branches, and the full source exceptional-data correspondence, cannot be silently inferred. No LaTeX correction is prescribed by these proofs.

`Checkpoint_96_IntermediateCircleApproximation.md`

Checkpoint 96: Intermediate-denominator approximation for the genuine circle model

This checkpoint proves the intermediate-denominator part of the actual circle approximation. Suppose a reduced rational r=a/q approximates the chosen real representative with |xi-r|<=R/(q*N^2), and

```
R < q <= R^(11/10).
```

The already proved inverse-fifth progression estimate controls the difference between the actual annular von Mangoldt multiplier and its genuine Gauss model. The unconditional Gauss bounds give model size at most C_G*q^(-5/12), which is at most C_G*R^(-5/12). Lean therefore proves a bound for the actual multiplier by (4+(2+4*pi)*C)/R^5+C_G*R^(-5/12).

On the branch outside all small-denominator major arcs, including all integer lifts relevant for the representative in [-1,2], checkpoint 94 bounds the actual circle model by circleModelTailBudget(R). Subtracting it gives the same circleApproxBudget(C,R) used on the major-arc branch. The outside-arc assumption is an explicit geometric case condition, not an assumed minor-arc estimate. The approximating rational need not itself belong to the small-denominator set.

The uniform theorem specializes to the exact source rational set and source scale. For C>=0, c>0 and A>=0, one threshold in N, independent of Q and the permitted data, gives the bound 2^A*Q^(-1/2)*(1+log N)^(-A) whenever Q>=1, log Q <= (min(c/7,1)/8)*sqrt(log N), and the displayed raw progression-prefix inequality holds at the approximating denominator throughout [N/2,N]. This is the same kind of explicit deep input already used in the preceding source-range major-arc work; no new analytic axiom is introduced.

The major-arc and intermediate branches now refer to the genuine periodized circle model, with precise finite rational indexing and all integer shifts accounted for. The existence/selection of an appropriate rational approximation is not asserted by this checkpoint. The branch q>R^(11/10), including the unresolved full-range minor-arc deduction, remains open. Consequently full Lemma 6.5, global Lemma 6.9, sharp low 6.14, multifrequency 6.16, high/maximal 6.21, Proposition 4.19 and Theorem 1.1 remain unproved. The full exceptional-parameter/source correspondence also remains open. No new manuscript correction has been established.

The already displayed raw progression-prefix estimate is consumed as a theorem hypothesis; it remains unproved. No new external analytic estimate or own-paper lemma is assumed.

`Checkpoint_97_GhoshBalancedBound.md`

Checkpoint 97: A fixed-epsilon Ghosh bound in the balanced denominator range

This checkpoint introduces the explicit Ghosh quadratic bracket 1/q+x^(-1/2)+q/x^2 and proves that, throughout x^(1/2)<=q<=x^(3/2), it is at most 3*x^(-1/2). Raising to the fourth power root gives 3^(1/4)*x^(-1/8), with positivity proved rather than assumed.

The actual annular von Mangoldt circle multiplier is related exactly to the positive-phase Ren sum on (N/2,N], with its 1/N normalization. From the displayed raw Ghosh estimate with the fixed epsilon=1/16, Lean proves a bound (B*3^(1/4)/2)*(N/2)^(-1/16) for this actual multiplier in the balanced denominator range. The epsilon is fixed once; it is never chosen as a function of N. This gives a polynomial saving in that range.

The deep Ghosh estimate is not formalized or added as an axiom. It is an explicit inequality hypothesis of the consuming theorems. Its source is A. Ghosh, The Distribution of alpha p^2 Modulo 1, Proc. London Math. Soc. 42 (1981), Theorem 2, with coprimality and strict approximation error <1/q^2. The original article's first-page transcription was inspected at https://www.academia.edu/60387191/The_Distribution_of_p2_Modulo_1 and its publisher identity is https://doi.org/10.1112/plms/s3-42.2.252. The annular form is also explicitly displayed as equation (1.4) of Xiumin Ren's author preprint https://www.math.hku.hk/imrwww/IMRPreprintSeries/2004/IMR2004-9.pdf. The consumer assumes the displayed raw inequality itself; it does not assert it for arbitrary incompatible choices of q and xi. Exact rational selection and compatibility are subsequent tasks.

This supplies the complementary balanced-denominator branch, not yet a full minor-arc theorem. A new approximation at precision x^(-3/2) is planned so that its larger denominators lie in this range. The smaller-denominator branch will use Ren, with its divisor prefactor controlled explicitly. The source's stronger printed minor-arc estimate remains open; no LaTeX correction is established by this checkpoint.

ses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_98_ExponentGeometricBound.md

Checkpoint 98: Uniform prime-power exponent growth

This is the first step of an unconditional divisor-growth proof needed to retain Ren's divisor prefactor. For every fixed real ratio r>1, Lean proves a single constant A>=1 such that n+1<=A*r^n for every natural exponent n, including n=0 and the whole finite initial range. The eventual estimate is obtained from a proved Mathlib asymptotic limit; the early exponents are bounded explicitly by the selected threshold. No number-theoretic hypothesis enters.

Real powers commute with natural powers on nonnegative bases. Applying the geometric estimate at ratio 2^epsilon, and using p>=2, gives a constant A independent of the prime p and exponent n such that n+1<=A*(p^n)^epsilon. The exponent epsilon is a fixed positive real number, not a parameter chosen with the denominator or scale. This is the local prime-power inequality that will be multiplied over the factorization of q.

This checkpoint proves these uniform local growth statements only. The full divisor count and its 3/2 power are addressed subsequently. It does not assume a divisor bound, PNT, a progression estimate or an exponential-sum theorem, and it does not close the minor-arc or main theorem gaps on its own.

Checkpoint_99_DivisorProductGrowth.md

Checkpoint 99: An unconditional uniform subpower bound for the divisor count

The exact divisor count is expressed as the product of exponent-plus-one factors over the distinct prime divisors of q. Using the uniform prime-power estimate of checkpoint 98, Lean bounds this product by A^omega(q)*q^epsilon. The product of prime powers is exactly q, with natural-to-real casts and real-power multiplication justified.

The existing elementary absorption of a fixed A^omega(q) into a small positive power of q then proves: for every fixed epsilon>0, there is C>0 such that tau(q)<=C*q^epsilon for every positive integer q. The constant is independent of q, includes q=1, and is selected before the denominator. The proof uses only

unique factorization, finite products and proved asymptotic limits; it assumes no divisor bound, PNT or analytic number-theory theorem.

This is a supporting arithmetic estimate needed for Ren's prefactor. It does not assert a bound for a prime exponential sum without its explicit deep-input hypothesis, or close the full minor-arc or headline theorem gaps.

`Checkpoint_100_RenDivisorBudget.md`

Checkpoint 100: A fixed subpower budget for the exact Ren divisor prefactor

The unconditional divisor bound is raised to an arbitrary fixed positive real power gamma, retaining a constant uniform in the positive integer q. For each epsilon>0, Lean proves tau(q)^gamma<=C*q^epsilon by applying the previous bound at epsilon/gamma and justifying all real-power identities.

For the exact Ren prefactor gamma=3/2, a positive constant renDivisorConstant is selected from the proved existence theorem at the fixed exponent 1/12. Its positivity and the bound tau(q)^(3/2)<=renDivisorConstant*q^(1/12) are proved for every positive q. Neither exponent varies with q or N. No external analytic hypothesis is involved.

The aim is to insert this controlled prefactor into the subsequent Ren branch. This checkpoint does not claim that the q^(1/12) loss can be ignored or absorbed without further estimates. Full minor-arc and global approximation deductions remain open at this stage.

No own-paper analytic conclusion is assumed.

`Checkpoint_101_BalancedEffectiveDenominator.md`

Checkpoint 101: Effective-denominator bounds for the balanced approximation

This checkpoint proves the elementary geometry for a new balanced rational approximation. If x>0, 0<q<=sqrt(x), and the real offset satisfies |theta|<=1/(q*x^(3/2)), then Ren's effective denominator T=q*(1+|theta|*x^2) lies between q and 2*sqrt(x). The upper bound is exact and uses the real-power identity x^2=x^(3/2)*x^(1/2).

A complementary lower bound is proved: T>=R/4 whenever either q>=R or |theta|>=R/(4*q*x^2), for x>0 and R>=0. With N=2*x, the latter threshold is exactly the width R/(q*N^2) of a source major arc. Thus being outside the small-denominator arcs will force T large, even when the newly selected q itself is small.

These statements are inequalities for the actual previously defined renEffectiveDenominator, not assumptions about an abstract replacement. They use no exponential-sum or distribution theorem. Selecting a compatible rational approximation and connecting the outside-arc condition are separate subsequent tasks.

No own-paper analytic

conclusion is assumed.

`Checkpoint_102_BalancedRationalApproximation.md`

Checkpoint 102: A proved rational selection at balanced precision

Mathlib's proved Dirichlet approximation theorem is applied with the integer cutoff floor(x^(3/2)). For every x>=1 and every real xi, Lean constructs a reduced rational r with den(r)<=x^(3/2), |xi-r|<=1/(den(r)*x^(3/2)), and the strict bound |xi-r|<1/den(r)^2. Floor errors, positive denominators and the cutoff's positivity are proved explicitly. This applies to rational and irrational xi alike.

The annular specialization sets x=N/2 for natural N>=2. If xi lies in [0,1], the selected rational lies in [-1,2]. No rational approximation is supplied as an unproved existence assumption. The strict reciprocal-square bound is the compatibility needed for the external Ghosh estimate; the finer x^(-3/2) precision also controls Ren's effective denominator in the smaller-denominator branch.

This is a new approximation used by the complementary argument; it need not be the manuscript's original approximant. No change to the manuscript is prescribed. The prime exponential-sum estimates remain explicit deep-input hypotheses.

`Checkpoint_103_RenSmallDenominatorTerms.md`

Checkpoint 103: The first two normalized Ren terms with the divisor loss retained

The first two terms of Ren's three-term bracket are bounded while retaining the q^(1/12) loss proved necessary for its divisor prefactor. For x>0 and 0<=q<=sqrt(x), Lean proves q^(1/12)<=x^(1/24). If the effective denominator T<=2*sqrt(x), then sqrt(T)<=sqrt(2)*x^(1/4).

These yield the exact normalized inequalities

```
q^(1/12)\*sqrt(x)\*sqrt(T)/x <= sqrt(2)\*x^(-5/24),
q^(1/12)\*x^(4/5)/x <= x^(-19/120).
```

All real-power identities, positivity conditions and normalization by x are checked in Lean. The denominator q is a real parameter in these inequalities, allowing the later natural denominator to be substituted without changing the statement. No external analytic estimate is assumed. The remaining inverse-effective-denominator term is handled separately before the bracket is recombined.

Verification

All 170 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3692-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 993 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 172 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_104_RenInverseEffectiveTerm.md`

Checkpoint 104: The inverse effective-denominator term with divisor loss retained

The inverse-effective-denominator term is controlled with the divisor loss included. If q>=0, R>0, q<=T and R/4<=T, then

```
q^(1/12)/sqrt(T) <= 4^(5/12)\*R^(-5/12).
```

The proof first replaces q^(1/12) by T^(1/12), giving T^(-5/12), and then uses the lower bound on T. This avoids inserting an uncontrolled q^epsilon factor into an R-only estimate. The exact normalized third term q^(1/12)*(x/sqrt(T))/x satisfies the same bound for x>0; its cancellation is justified.

These are unconditional real inequalities. In the later application, the new approximation gives the upper bound on T and the outside-major-arc condition gives the lower bound. No bound on a prime sum is inferred until its explicit Ren hypothesis has been supplied.

Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_105_RenBalancedBracket.md`

Checkpoint 105: The complete weighted Ren bracket in the balanced regime

The three previously proved weighted term bounds are combined into the explicit renBalancedBudget(x,R): sqrt(2)*x^(-5/24)+x^(-19/120)+4^(5/12)*R^(-5/12). Its nonnegativity is proved on nonnegative bases.

For positive x,R, 0<=q<=sqrt(x), q<=T<=2*sqrt(x), and T>=R/4, Lean proves q^(1/12)*renQuadraticBracket(x,T)/x<=renBalancedBudget(x,R). A second theorem substitutes the actual effective denominator associated to an approximation satisfying |theta|<=1/(q*x^(3/2)). The upper bound and q<=T then come from the checked geometry, rather than extra analytic assumptions.

This is an unconditional recombination of inequalities. The next consuming theorem inserts the raw Ren exponential-sum estimate and its genuine divisor prefactor; no prime-sum bound is assumed or asserted in the present statements.

No own-paper analytic conclusion is assumed.

`Checkpoint_106_AnnularRenBalancedBound.md`

Checkpoint 106: The actual annular multiplier under the raw Ren estimate

This checkpoint applies the explicit Ren exponential-sum hypothesis to the actual annular von Mangoldt circle multiplier, using the newly proved weighted bracket estimate and the unconditional divisor budget.

For N>=4, x=N/2, q<=sqrt(x), approximation precision |theta|<=1/(q*x^(3/2)), and effective denominator at least R/4, Lean proves

```
norm(actual annular multiplier) <= (C\*renDivisorConstant/2)\*(log x)^c\*renBalancedBudget(x,R).
```

The factor 1/2 comes from the exact N=2*x normalization. Positivity of the bracket, logarithmic base and selected divisor constant is proved. The q^(1/12) loss is consumed by the weighted estimates and has not been discarded. The raw Ren inequality still appears explicitly in the theorem hypothesis with its full tau(q)^(3/2) prefactor.

The theorem consumes a compatible raw estimate; it does not assert Ren's theorem for arbitrary unrelated xi and theta. Rational compatibility will be supplied by the selected approximation. No own-paper minor-arc conclusion or additional mathematical axiom is used.

No own-paper analytic conclusion is assumed.

`Checkpoint_107_SourceScaleFourthPower.md`

Checkpoint 107: A uniform fourth-power budget for the source scale

The source-range major-arc parameter budget also controls the new complementary argument. For N>=4, R>=1, log N>=1 and R^5*log N<=sqrt(N), Lean proves R^4<=N/2. The proof retains the exact N/2 annulus: R^4<=R^5<=R^5*log N<=sqrt N<=N/2.

A real-power consequence is proved for every a>=0: if R>0 and R^4<=x, then x^(-a)<=R^(-4*a). This will convert the polynomial savings from Ren and Ghosh into powers of R without changing a fixed epsilon with N.

The final theorem supplies a single natural threshold, independent of Q, for the actual source scale R=sourceMajorArcScale(N,Q), over the same allowed Q range as the already proved progression budget. Positivity, log N>=1 and N>=4 are supplied by proved eventual limits and the existing parameter theorem. No deep estimate is added here.

No own-paper analytic conclusion is assumed.

`Checkpoint_108_CanonicalApproximationLift.md`

Checkpoint 108: Canonical rational centers for an arbitrary selected approximation

Any rational approximation r is normalized to its exact fractional part, a canonical rational in [0,1). Its reduced denominator is unchanged by this normalization, using Mathlib's proved rational-floor theorem. The frequency offset is exactly rewritten as an integer lift of that canonical center:

```
xi-r = xi-floor(r)-fract(r).
```

Lean proves that if den(r)<=R with R>=0, then fract(r) belongs to the exact finite sourceRationalCenters(R). The cast of the rational fractional part is explicit, avoiding an implicit change from rational to real floor operations.

This is the arithmetic bridge allowing a newly selected rational, whose numerator may fall outside the canonical interval, to be tested against all lifted source major arcs. It uses no prime-distribution or exponential-sum input.

No own-paper analytic conclusion is assumed.

Checkpoint_109_OutsideSourceArcs.md

Checkpoint 109: Exclusion from all lifted source arcs and the effective lower bound

OutsideSourceMajorArcs is defined using the exact finite source rational set and every integer lift. It requires R/(den(r)*N^2)<=|xi+k-r| for each center and integer k. This is an explicit geometric branch condition, not a minor-arc analytic estimate.

For any rational r with den(r)<=R, the canonical-fractional-part bridge gives the same lower bound for |xi-r|. Consequently, for every rational r, the actual Ren effective denominator at x=N/2 is at least R/4: either den(r)>=R, or exclusion from its lifted small-denominator arc gives the bound. There is no restriction that the selected r already be canonical.

Finally, the existing circle-model outside-arc theorem is specialized to this exact set and all-lift condition. It bounds the genuine periodized model by circleModelTailBudget(R), including the denominator-one center and all shifted copies. The beta/coefficient bounds and representative interval [-1,2] remain explicit. No new analytic hypothesis is assumed.

Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_110_RenScaleAbsorption.md

Checkpoint 110: Converting the balanced Ren budget to a scale-only bound

The explicit balanced Ren budget is converted to a pure power of R under R>=1 and R^4<=x. The previously proved fourth-power comparison gives x^(-5/24)<=R^(-5/6) and x^(-19/120)<=R^(-19/30). Both are at most R^(-5/12).

Lean therefore proves renBalancedBudget(x,R)<=renGeometryConstant*R^(-5/12), with the fixed positive constant sqrt(2)+1+4^(5/12). A weaker quarter-power consequence is also recorded for later comparison with Ghosh. The fixed exponents and constants are preserved, and no uncontrolled N^epsilon loss is absorbed into a subpolynomial scale.

These are unconditional scalar deductions. They become estimates for the actual multiplier only when the preceding consuming theorem's explicit Ren inequality is supplied.

No own-paper analytic conclusion is assumed.

`Checkpoint_111_GhoshScaleAbsorption.md`

Checkpoint 111: Converting the balanced Ghosh saving to a scale-only bound

The balanced Ghosh saving (N/2)^(-1/16) is converted to R^(-1/4) whenever R>0 and R^4<=N/2. The fixed constant B*3^(1/4)/2 is defined and proved nonnegative for B>=0.

The resulting theorem bounds the actual annular von Mangoldt circle multiplier for (N/2)^(1/2)<=q<=(N/2)^(3/2), conditional on the displayed raw Ghosh inequality at the fixed epsilon 1/16. The fourth-power hypothesis is exactly the source-scale budget proved earlier. No additional outside-arc hypothesis is needed on this balanced-denominator branch.

Ghosh's deep estimate remains a hypothesis, not an added axiom or a placeholder. The new step is the checked scale conversion and its application to the genuine multiplier, uniform in the permitted denominator.

Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_112_AnnularRenScaleBound.md

Checkpoint 112: The small-denominator Ren branch at the actual source scale

The raw Ren consuming theorem is combined with the proved fourth-power scale absorption. The actual annular multiplier is bounded by renSourceConstant(C)*(log(N/2))^c*R^(-5/12), provided N>=4, R>=1, R^4<=N/2, the selected denominator q<=sqrt(N/2), the balanced approximation precision holds, and its effective denominator is at least R/4.

The constant is the explicit product (C*renDivisorConstant/2)*renGeometryConstant; its nonnegativity is proved for C>=0. All divisor and logarithmic factors remain accounted for. The supplied Ren inequality involves the actual annular exponential sum at the same xi and theta as the chosen approximation.

This is the small-denominator analytic branch of the complementary argument. The deep raw estimate is explicit; the paper's own minor-arc conclusion is not assumed. The rational selection and outside-arc geometry will supply the remaining geometric hypotheses in the subsequent assembly.

No own-paper analytic conclusion is assumed.

Checkpoint_113_ComplementaryMinorArcBound.md

Checkpoint 113: An alternative full-range minor-arc deduction under raw deep estimates

This checkpoint completes an alternative full-range minor-arc deduction for the actual annular von Mangoldt circle multiplier, conditional on displayed raw Ren and Ghosh estimates. The two input predicates state precise inequalities for the actual sum at compatible rational approximations. They are propositions in theorem hypotheses, not mathematical axioms.

Lean selects a reduced rational at precision x^(-3/2), x=N/2, using the proved existence theorem. If its denominator is at most sqrt(x), the all-lift outside-source-arc condition supplies the lower effective-denominator bound and the Ren branch applies. If its denominator exceeds sqrt(x), it lies in the proved balanced Ghosh range and satisfies the strict reciprocal-square approximation condition. There is no uncovered denominator range.

For N>=4, R>=1 and R^4<=N/2, the result is

```
norm(actual annular multiplier) <= renSourceConstant(C)\*(log(N/2))^c\*R^(-5/12)
                                 + ghoshSourceConstant(B)\*R^(-1/4).
```

The combined budget is proved nonnegative. The fixed epsilon in Ghosh is 1/16; the divisor-growth epsilon is fixed at 1/12. Neither depends on N. The estimate is valid on the full complement of the small-denominator lifted major arcs and does not rely on the manuscript's original approximant. It is weaker than the stronger printed minor-arc formula in Lemma 6.5, which remains open; it is intended to suffice for global approximation Lemma 6.9. No manuscript replacement is prescribed on this basis.

`Checkpoint_114_LogPowerAbsorption.md`

Checkpoint 114: Absorbing fixed logarithmic and power budgets

Lean proves that every fixed real power of log R is eventually bounded by R^epsilon for any fixed epsilon>0. The proof consumes a proved Mathlib little-o limit and retains explicit positivity before simplifying norms. It does not use a number-theoretic asymptotic assumption.

Two constant-absorption statements are also proved. If K>=0 and a<b, then K*R^a<=R^b eventually; and if two nonnegative weighted powers both have exponent below b, their sum is eventually at most R^b. The finite constants are absorbed into thresholds, never by changing exponents with R.

These supporting inequalities will absorb the genuine logarithmic factor in the complementary minor budget. They do not by themselves assert an estimate for a prime exponential sum.

`Checkpoint_115_SourceLogPowerBudget.md`

Checkpoint 115: Uniform logarithmic absorption at the actual source scale

For the actual source scale R=max(exp((log N)^(1/10)),Q^8), Lean proves log R>=(log N)^(1/10). Hence, for N>=1 and every d>=0, (log N)^d<=(log R)^(10*d). All real-power compositions and the nonnegative logarithmic bases are justified.

Combining this with the preceding logarithmic absorption and the source scale's uniform lower growth gives one natural threshold, independent of Q, for

```
(log(N/2))^d <= R^epsilon,
```

for every fixed d>=0 and epsilon>0. The statement quantifies over all real Q; no Q-dependent threshold is hidden. This handles Ren's fixed logarithmic loss at the exact annular scale.

The proof is unconditional and uses no PNT or prime exponential-sum hypothesis. It prepares the uniform error budget needed after the complementary geometric and analytic branches have been assembled.

All 1025 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 184 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains

two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_116_UniformComplementaryBudget.md`

Checkpoint 116: A uniform source-scale complementary minor budget

The complementary minor budget is proved uniformly small at the actual source scale. The logarithmic factor in Ren's term is bounded by R^(1/12), turning that contribution into renSourceConstant(C)*R^(-1/3). Ghosh's contribution is ghoshSourceConstant(B)*R^(-1/4). Their sum is eventually at most R^(-1/6), uniformly over Q, for fixed C,B,d>=0.

Substituting the already proved source-scale logarithmic rate gives the desired Q^(-1/2)*(1+log N)^(-A) bound with factor 2^A, for every A>=0 and Q>=1. The threshold depends on the fixed constants and A but not on Q, the selected rational or the frequency.

This checkpoint controls the explicit scalar budget. The actual minor-arc multiplier theorem still requires its displayed raw Ren and Ghosh inputs and geometric outside-arc condition; those are not hidden inside the scalar estimate. The stronger printed minor-arc formula remains open.

Checkpoint notes 117-191

Checkpoint_117_UniformCircleMinorError.md

Checkpoint 117: A uniform error bound on the full circle minor-arc complement

The alternative minor-arc estimate is transferred to the genuine periodized circle error. On the full all-lift complement of the source major arcs, the actual multiplier is bounded by complementaryMinorBudget, and the actual circle model by circleModelTailBudget. Their difference has norm at most the sum; no unperiodized model is substituted.

A separate uniform logarithmic bound is proved for circleModelTailBudget. Combining it with the complementary budget, the uniform source fourth-power condition and the displayed raw Ren/Ghosh inputs gives, for fixed nonnegative C,B,d and every A>=0, the bound

```
norm(circle error) <= 2\*2^A\*Q^(-1/2)\*(1+log N)^(-A).
```

One threshold in N works for all permitted Q, beta, character/coefficient data and frequencies on this geometric branch. The Q range is the same small-constant exp(sqrt(log N)) range as in the major-arc work. The coefficient and beta bounds, representative interval [-1,2], outside-arc condition and raw inputs are explicit. The stronger printed minor formula remains open; this alternative estimate is sufficient for the next global circle approximation assembly.

Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_118_WrappedCircleMajorUniform.md

Checkpoint 118: The uniform error bound on all lifted major arcs

The actual continuous circle error is exactly unchanged when an integer is added to a real representative. Lean proves this from the quotient identity rather than asserting periodicity of the underlying real oscillatory integral.

The conditional major-arc uniform theorem is then extended to any lifted major arc, with arbitrary integer k and condition |xi+k-r0|<=R/(den(r0)*N^2). Its conclusion concerns the original circle point xi. The

same uniform N threshold, all-Q range and raw progression-prefix hypothesis are retained, and shifted copies of the denominator-one center are included.

This is the boundary-compatible major branch used by the global major/minor case split. No outside-arc or minor conclusion is assumed, and no new deep input is introduced.

No own-paper analytic conclusion is assumed.

`Checkpoint_119_GlobalCircleApproximation.md`

Checkpoint 119: A conditional global pointwise approximation on the circle

The genuine circle error is now bounded at every representative xi in [0,1], conditional on the displayed progression-prefix, Ren and Ghosh inputs. Lean makes a complete case split over the exact finite source rational set and all integer lifts. If a lifted major arc contains xi, the wrapped conditional major theorem applies. Otherwise the logical negation supplies the outside-arc condition needed for the alternative minor theorem.

For every fixed P,C,B,d>=0, c>0 and A>=0, one natural threshold works uniformly in all permitted Q and character/coefficient/beta data, giving

```
norm(actual circle error) <= 2\*2^A\*Q^(-1/2)\*(1+log N)^(-A).
```

The progression estimate must hold for every source denominator and every real endpoint in [N/2,N] with the same scale data. The Ren/Ghosh inequalities are explicit pointwise hypotheses at the compatible approximants, not hypotheses asserting the desired error conclusion. There is no gap between the two cases and no assumption of the paper's own minor-arc or approximation lemma.

This completes the conditional global pointwise analytic deduction for the genuine circle model. The next steps extend the bound to every circle point and to the actual bounded l2 operator. The stronger printed Lemma 6.5, full exceptional-data/source correspondence and sharp low/high/maximal inputs remain open; Theorem 1.1 is not proved.

Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_120_CircleFundamentalBounds.md

Checkpoint 120: From a fundamental representative interval to all circle points

Every point of PrimeCircle is represented by a real xi in the half-open interval [0,1), using Mathlib's proved quotient equivalence. Consequently a bound for a continuous circle function on the closed representative interval [0,1] is a bound at every circle point. Endpoints are included consistently.

The same fundamental-interval bound controls the norm of the actual integer l2 multiplier operator through the previously proved negative-phase Fourier isometry. The function is an actual continuous circle symbol and the operator acts on all l2 inputs; no finite-input or formal-symbol substitute is used.

These quotient and operator-transfer facts introduce no analytic hypothesis or new mathematical axiom. They allow the newly proved conditional global error bound to yield an actual all-input operator estimate.

Verification

All 187 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3709-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1036 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 189 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_121_CircleApproximationData.md

Checkpoint 121: A conditional global approximation for the actual l2 operator

The explicit deep analytic inputs are collected in CircleAnalyticInputs: 0<beta<=1, coefficient norms at most one, the actual raw progression-prefix inequality for every source rational denominator and every real endpoint in [N/2,N], and the compatible raw Ren/Ghosh inequalities for every representative xi in [0,1]. The structure contains no approximation, operator-norm or own-paper lemma conclusion.

From these inputs, Lean proves a bound for the actual circle error at every circle point. It then proves the norm bound for the genuine l2 error operator, with one N threshold before all permitted Q and input data:

```
norm(error operator) <= 2\*2^A\*Q^(-1/2)\*(1+log N)^(-A).
```

This is an end-to-end conditional analytic deduction for the periodized approximation: exact finite rational indexing, compatible rational selection, both major and alternative minor branches, all integer lifts, the circle representative bridge and the actual Fourier operator are included. The deep number-theory inputs remain hypotheses, as authorized, rather than added axioms or placeholders.

The stronger printed minor estimate of Lemma 6.5 has not been established, and the full source exceptional-parameter and double-sum correspondence is not silently certified by the input structure. Sharp low/high/multifrequency/maximal estimates and Theorem 1.1 remain open. This checkpoint performs a fresh full project rebuild and complete axiom/source audits before packaging.

No own-paper analytic conclusion is assumed.

Checkpoint_122_SourceRangeMonotonicity.md

Checkpoint 122: Monotonicity of the allowed Q range and source cutoff

The allowed Q range is proved stable as the arithmetic scale increases. The coefficient min(c/7,1)/8 is positive for c>0, and monotonicity of log and sqrt shows that a Q allowed at N is allowed at every M>=N>=1.

The source cutoff itself is also monotone in N on N>=1. This follows from monotonicity of log, the fixed positive real power 1/10, exp and max. These facts allow one Q and one starting-scale condition to be used along an entire dyadic tail, rather than imposing unrelated conditions at each scale.

The proofs are unconditional scalar geometry. They introduce no prime-distribution or operator-norm assumptions and do not claim the remaining sharp high/low estimates.

`Checkpoint_123_DyadicLogarithmicBudget.md`

Checkpoint 123: Exact dyadic logarithms and inverse-power comparison

Lean records the exact arithmetic and logarithmic identities for dyadic scales 2^j. In particular log(2^j)=j*log 2 and monotonicity in the exponent is proved.

Since 0<log 2<=1, the bound log 2*(j+1)<=1+log(2^j) holds even at j=0. For every A>=0 this gives

```
(1+log(2^j))^(-A) <= (log 2)^(-A)\*(j+1)^(-A).
```

The explicit constant will convert the conditional global operator-error bound to a summable sequence in the dyadic exponent. No asymptotic substitution of j for log N is left informal.

No own-paper analytic conclusion is assumed.

Checkpoint_124_DyadicCircleErrorBudget.md

Checkpoint 124: Quantitative decay of the actual dyadic error operators

An actual dyadic family of l2 error operators is defined from the genuine periodized circle model, with character, coefficient and beta data allowed to vary with the dyadic exponent. One positive constant dyadicErrorConstant(A)=2*2^A*(log 2)^(-A) is selected explicitly.

The global conditional l2 approximation, the upward stability of the allowed Q range and the dyadic logarithmic comparison prove an operator norm bound

```
norm(E_(2^j)) <= dyadicErrorConstant(A)\*Q^(-1/2)\*(j+1)^(-A)
```

for every j beyond a chosen starting exponent, under the explicit analytic inputs at those scales. A single arithmetic threshold is chosen before the starting exponent, Q and all scale-dependent data. The Q restriction is required only at the starting scale and is then proved at later scales.

These are genuine bounded operators acting on every l2 input. The external progression, Ren and Ghosh inputs remain explicit via CircleAnalyticInputs; no maximal-error or high/low conclusion is assumed.

Checkpoint_125_ReciprocalSquareFiniteTail.md

Checkpoint 125: A finite reciprocal-square tail with exact telescoping

The quantitative series estimate needed for the dyadic error tail begins with a checked telescoping inequality:

```
1/(j+1)^2 <= 2\*(1/(j+1)-1/(j+2)).
```

Lean proves the exact sum of the reciprocal differences on every integer interval [J,K), including the empty interval. It follows that the sum of 1/(j+1)^2 on that interval is at most 2/(J+1). This holds for all natural endpoints, with no hidden J>0 condition.

The estimates are elementary finite real inequalities. They will provide an explicit infinite-tail bound rather than relying only on qualitative convergence of a p-series.

`Checkpoint_126_ReciprocalSquareInfiniteTail.md`

Checkpoint 126: A quantitative infinite reciprocal-square tail

Finite sums indexed by a shifted range are identified exactly with sums on [J,J+K). The reciprocal-square finite-tail bound then bounds every partial sum of the shifted nonnegative series.

Lean proves both summability of the series sum_j 1/(J+j+1)^2 and the explicit bound 2/(J+1). The proof works for every natural J, including J=0. It uses the proved nonnegative-series criterion and the finite telescoping estimate; no numerical approximation or assumed zeta value is involved.

This prepares a quantitative infinite envelope for the actual dyadic operator errors.

Checkpoint_127_WeightedPowerFiniteTail.md

Checkpoint 127: Weighted real-power finite tails

For every fixed real s>=2 and j>=J, Lean splits (j+1)^(-s) into a nonincreasing weight and a reciprocal square. The weight is bounded by (J+1)^(2-s), giving

```
sum_(J<=j<K) (j+1)^(-s) <= 2\*(J+1)^(1-s).
```

All real-power identities and positivity conditions are proved. The bound holds for arbitrary natural endpoints, including empty intervals and the starting exponent zero. It retains the exact tail exponent needed for a maximal-error estimate with arbitrary logarithmic saving.

The statement is an unconditional scalar series bound, not an assumed operator inequality.

Checkpoint_128_WeightedPowerInfiniteTail.md

Checkpoint 128: Summability and quantitative weighted infinite tails

The weighted finite-tail estimate is passed to the infinite nonnegative series. For every real s>=2 and every natural starting exponent J, Lean proves summability and

```
sum_j (J+j+1)^(-s) <= 2\*(J+1)^(1-s).
```

There is no dependence on an unbounded finite truncation and no interchange of conditionally convergent sums. The proof uses bounded nonnegative partial sums, so both existence and the quantitative tail are checked.

This is the scalar summability input for the countable l2 envelope constructed next.

Checkpoint_129_OperatorDecaySeries.md

Checkpoint 129: Absolute summability and quantitative tails of operator norms

An arbitrary family of actual bounded l2 operators with a fixed power decay norm(T_j)<=K*(j+1)^(-s), s>=2, has a summable norm tail. Lean proves both norm summability and convergence of the operator series in the Banach space of continuous linear maps.

The exact quantitative tail is

```
sum_j norm(T_(J+j)) <= 2\*K\*(J+1)^(1-s).
```

The estimate follows from the checked weighted scalar series and applies to every natural starting exponent. This is the summability mechanism for the actual dyadic error family, not an assumed maximal theorem. The actual decay bound from the conditional global approximation will be supplied at the later application.

No own-paper analytic conclusion is assumed.

`Checkpoint_130_CountableOperatorEnvelope.md`

Checkpoint 130: A genuine countable positive l2 operator envelope

A countable positive l2 envelope is constructed as the Banach-space sum of the existing magnitudeL2 realizations of T_j f. Under summability of the operator norms, Lean proves that both the vector magnitudes and their norms are summable for every complex l2 input f.

The resulting genuine real l2 vector has norm at most (sum_j norm(T_j))*norm(f). Completeness and absolute summability justify the vector sum; it is not treated as a formal series or a finite maximum. The magnitude construction already present in the project is reused.

The next checkpoints identify every coordinate of this vector sum and show that it dominates the true countable maximal function. No analytic number-theory or own-paper maximal hypothesis enters this functional-analytic construction.

No own-paper analytic conclusion is assumed.

`Checkpoint_131_CountableEnvelopeCoordinates.md`

Checkpoint 131: Exact coordinate identities for the countable l2 envelope

Evaluation at each integer coordinate is a continuous linear map on real l2. Lean uses that map to commute evaluation with the proved convergent vector series, identifying the countable envelope exactly with sum_j norm(T_j f(x)) at every integer x.

The coordinate series is proved summable, and its absolute value is bounded by (sum_j norm(T_j))*norm(f). There is no almost-everywhere exception or unjustified interchange of a non-summable series with evaluation.

These are the coordinate identities needed to prove domination of each operator output and of the true countable supremum. They use only the displayed operator-norm summability assumption, which is subsequently supplied by the quantitative decay of the actual error operators.

`Checkpoint_132_CountableEnvelopeDomination.md`

Checkpoint 132: Pointwise domination by the countable envelope

The countable envelope is proved nonnegative at every integer and to dominate norm(T_j f(x)) for every index j. Every existing finite operator envelope is also bounded pointwise by the countable envelope.

The proofs use the exact coordinate series and its established summability. In particular, the finite-to-countable passage is justified for all l2 inputs rather than only for finitely supported functions. The bound contains all indices and has no dependence on the size of a finite truncation.

This is a functional-analytic consequence of norm summability, not a new deep analytic input.

`Checkpoint_133_CountableOperatorMaximum.md`

Checkpoint 133: A bounded true countable maximal function

The actual pointwise countable supremum sup_j norm(T_j f(x)) is defined as operatorMaximalValue. Lean proves the set of values is bounded above by the countable envelope before using conditional supremum inequalities over the real numbers.

The supremum dominates every operator output, is nonnegative, and is at most the countable envelope. This rules out interpreting an unbounded real supremum through a default total definition. All statements require and use summability of the operator norms to supply a genuine bound.

The next step proves that this actual maximal function, rather than just its majorant, belongs to l2.

`Checkpoint_135_OperatorMaximalNorm.md`

Checkpoint 135: An all-input countable maximal l2 bound

The l2 norm of the genuine countable maximal function is bounded by the norm of the countable positive envelope. Consequently,

```
norm(sup_j |T_j f|)_2 <= (sum_j norm(T_j))\*norm(f)_2.
```

Lean proves the pointwise nonnegativity and norm comparisons required for the l2 monotonicity argument. This is a complete countable all-input estimate under operator-norm summability, not merely an inequality for finite scale collections.

Applied to the proved dyadic error decay, it will provide the maximal error term without assuming a new multifrequency theorem. It does not bound the separate high or low operators.

`Checkpoint_136_OperatorMaximalSublinearity.md`

Checkpoint 136: Sublinearity of the actual countable maximal function

The true countable maximal function is proved subadditive on l2 inputs and invariant under replacing f by -f. A scalar bound operatorMaximalValue(z*f)<=|z|*operatorMaximalValue(f) is also proved for every complex scalar z.

The proofs use the linearity of the actual operators, the triangle inequality and the previously established boundedness of the real supremum. They do not assume that taking a countable supremum preserves linearity. These properties will give the final Lipschitz estimate for the maximal-error map.

`Checkpoint_138_MaximalTailMonotonicity.md`

Checkpoint 138: Monotonicity of the true countable maximal tails

Every tail of a norm-summable operator family is norm summable. Lean proves that moving the starting exponent from J to K>=J decreases the actual pointwise countable maximal function and its l2 norm.

The proof reindexes K+j exactly as J+(K-J+j); it does not discard indices informally or identify different scale-dependent data. The nonnegative real l2 realizations are compared using the pointwise inequalities already proved for the true supremum.

This supports quantitative approximation and continuity statements for dyadic error tails.

Checkpoint_139_DyadicErrorNormSeries.md

Checkpoint 139: Absolute norm summability of the actual dyadic error family

The actual dyadic circle-error family is proved absolutely summable in operator norm on every allowed tail. For a fixed exponent s>=2, the previously established decay and upward Q-range condition give

```
sum_j norm(E_(2^(J+j))) <= 2\*dyadicErrorConstant(s)\*Q^(-1/2)\*(J+1)^(1-s).
```

Both summability and the explicit bound are proved. The arithmetic threshold is chosen before J, Q, the input and all scale-dependent character, coefficient and beta data. CircleAnalyticInputs is required at the actual scales in the tail, with uniform displayed deep-input constants.

This supplies a genuine summable family for the countable maximal construction. No maximal-error inequality is assumed in the input.

Checkpoint_140_DyadicMaximalErrorPower.md

Checkpoint 140: The genuine countable maximal error with a power tail

The genuine countable maximal function of the actual dyadic circle-error operators is now realized as a real l2 vector for every complex l2 input. Lean proves

```
norm(sup_j |E_(2^(J+j)) f|)_2
  <= 2\*dyadicErrorConstant(s)\*Q^(-1/2)\*(J+1)^(1-s)\*norm(f)_2,
```

for s>=2, under the explicit scale-wise analytic inputs and the Q condition at the starting scale. There is one uniform arithmetic threshold before all J, Q and data. The supremum ranges over the entire infinite tail, and its coordinate equality is exact at every integer.

This is the maximal error component of the approximation argument. It does not provide the separate high-operator multifrequency bound or the low-kernel bound.

No own-paper analytic conclusion is assumed.

Checkpoint_141_DyadicMaximalErrorLog.md

Checkpoint 141: The conditional logarithmic dyadic maximal error estimate

The quantitative maximal error estimate is expressed in the manuscript's arithmetic-scale logarithm. Lean proves (J+1)^(1-(A+2))<=(1+log(2^J))^(-A) for every A>=0, including J=0.

Choosing s=A+2 in the full countable maximal bound gives a fixed positive constant C_A=2*dyadicErrorConstant(A+2) and the actual all-input estimate

```
norm(sup_j |E_(2^(J+j)) f|)_2
  <= C_A\*Q^(-1/2)\*(1+log(2^J))^(-A)\*norm(f)_2.
```

The Q range is imposed only at the starting scale and propagated rigorously. Character, coefficient and beta data may vary between scales, but the raw progression-prefix estimate uses one set of data throughout each scale's real endpoint interval. All external estimates remain explicit hypotheses.

This completes the conditional global approximation error and its dyadic maximal tail for the genuine circle model. The stronger printed Lemma 6.5, complete exceptional/source correspondence and the separate sharp low/high/multifrequency estimates remain open. Theorem 1.1 is not proved.

`Checkpoint_142_SummableOperatorLimits.md`

Checkpoint 142: Vanishing outputs of norm-summable operator families

A norm-summable family of bounded l2 operators produces an absolutely summable output series for every complex l2 input. Lean proves that the individual outputs tend to zero in l2 and at every integer coordinate.

The pointwise statement uses the continuity of coordinate evaluation on l2, so it does not rely on selecting an almost-everywhere subsequence. Applied to the norm-summable actual dyadic error tail, it shows that model approximation errors vanish along that full tail under the recorded analytic inputs.

These are consequences of the already checked summability mechanism; they are not claims of the paper's ergodic convergence theorem.

`Checkpoint_143_MaximalTailVanishing.md`

Checkpoint 143: Vanishing of the genuine countable maximal tails

The l2 norm of the true countable maximal tail tends to zero as the starting exponent tends to infinity for every norm-summable operator family and every l2 input. The proof bounds it by the tail sum of the operator norms times norm(f), and uses the proved vanishing of absolutely convergent series tails.

Lean also proves convergence of the maximal-tail vectors themselves to zero in real l2. The positive envelope and true supremum are not conflated, and no finite-scale limit is left unproved.

This gives a rigorous continuation property for the actual error family once its norm summability is supplied. It does not assert convergence of the remaining main model or prove an ergodic endpoint theorem.

Verification

All 210 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3735-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1095 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 212 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_144_DyadicModelDifference.md`

Checkpoint 144: Identifying the actual average-minus-model maximal error

The actual dyadic circle-model operator is defined with the same exact rational set and scale-dependent character/coefficient/beta data as the error family. Lean proves the operator identity

```
E_(2^j) = actual annular von Mangoldt average - circle model operator.
```

The identity is checked on all l2 inputs and every integer coordinate. The true countable maximal value of the error family is therefore exactly the supremum of the differences between those two actual operators on the dyadic tail.

This identifies the quantitative maximal bound with an approximation of the actual prime-power weighted square averages, rather than a bound for an abstractly named error family. It uses the existing negative-phase Fourier operator decomposition; no analytic conclusion is assumed.

Verification

All 211 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3736-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before

reuse; new/changed modules and the root are compiled. All 1098 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 213 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_145_QuantitativeErrorPairing.md`

Checkpoint 145: Finite-indicator pairing bounds for the conditional error operator

An actual l2 operator norm bound gives an explicit finite-indicator pairing bound b*sqrt(|F|)*sqrt(|G|), without kernel positivity. Lean proves this using the existing finite-indicator norm and discrete Cauchy--Schwarz estimate. Its normalized form is b*(|F||G|/L^2)^(1/2) after division by a positive spatial length L.

The conditional global circle-error norm theorem is then applied to obtain this finite-set error bound uniformly in the permitted Q and actual analytic inputs. The result is the quantitative error pairing needed in later restricted improving arguments.

This controls the error contribution only. The low and high contributions needed for Theorem 1.1 have not been supplied, so no full improving theorem is claimed.

<!-- checkpoint-verification -->

Verification

All 212 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3737-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1101 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 214 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_146_MaximalErrorLipschitz.md`

Checkpoint 146: Lipschitz continuity and final verification of the maximal error milestone

The genuine countable maximal map is proved Lipschitz on all complex l2 inputs when the operator norms are summable. Lean first proves the pointwise inequality

```
|sup_j |T_j f(x)| - sup_j |T_j g(x)|| <= sup_j |T_j(f-g)(x)|.
```

It then proves the l2 difference bound by (sum_j norm(T_j))*norm(f-g) and records the resulting LipschitzWith statement. This supplies a checked continuity property for the actual error maximal map, in addition to its norm estimate and tail convergence.

Checkpoints 97-146 establish an alternative full-complement minor argument using compatible balanced rational selection and explicit Ren/Ghosh estimates, a conditional global all-point and l2 approximation for the genuine periodized circle model, and a conditional quantitative countable dyadic maximal error bound with all-input realization. The raw progression-prefix, Ren and Ghosh inequalities remain unproved deep hypotheses. They are not added as mathematical axioms.

The stronger printed minor formula of Lemma 6.5 remains open; the new complementary argument is weaker but sufficient for the checked approximation deduction. Complete source exceptional-parameter and double-sum correspondence, sharp low 6.14, multifrequency 6.16, high/maximal 6.21, Proposition 4.19 and Theorem 1.1 remain open. No new manuscript error or mandatory LaTeX replacement is asserted. Lemma 3.21's two earlier PNT limits remain explicit; the separate PNT project has not been integrated by this batch.

This final checkpoint performs a fresh full rebuild and complete source/transitive-axiom audits. All fifty checkpoints are saved separately with their own proof expositions and verification histories. The combined report records exact scope, the meaningful mathematical milestones and the next unfinished targets.

Verification

All 213 project modules and the root were freshly rebuilt: 3738 jobs pass without warnings/errors. All 1104 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 215 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_147_TruncatedCohenBound.md`

Checkpoint 147: The truncated ordinary low arithmetic sum

The ordinary low-kernel arithmetic estimate is connected to the exact truncated denominator sum. Lean proves that the smooth absolute Cohen series is summable using its finite divisor support, dominates every finite sum whose prime factors lie below the cutoff, and gives an explicit uniform bound for the sum over 1 <= q <= Q by (cohenLogConstant/2)*log(Q+1). This is unconditional, uses the genuine correlation, and does not assume Mertens or the low-kernel conclusion. It supplies the arithmetic input for Proposition 6.14; the spatial kernel and source Fourier bridges remain to be proved.

Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_159_FiniteDecayTail.md`

Checkpoint 159: Finite near-far convolution decomposition

Proves the exact finite convolution split into a spatial ball and its complement, and a quantitative far-field estimate retaining the profile at the ball radius.

Checked declarations

Module	Named supporting theorems
FiniteDecayTail.lean	2

- `finiteConvolution_outside_ball`
- `finiteConvolution_split_ball`

<!-- checkpoint-verification -->

Verification

All 226 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3833-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1137 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 228 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_160_DyadicDecayShell.md`

Checkpoint 160: Polynomial decay on dyadic spatial shells

Proves the profile bound on a shell of radius 2^j H and the exact geometric normalization when the decay order is at least one. This supplies the summable shell weights needed for the local low estimate.

Checked declarations

Module	Named supporting theorems
DyadicDecayShell.lean	2

- `decayProfile_dyadic_shell`
- `dyadic_shell_normalization`

All 1208 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 263 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_195_PhysicalLowFarField.md`

Checkpoint 195: A quantitative far-field estimate for the physical low kernel

Proves the actual physical low convolution outside a radius R gains the tenth-order profile at R, in addition to the global l1 amplitude. No compact spatial support is assumed.

Checked declarations

Module	Named supporting theorems
PhysicalLowFarField.lean	1

- `physicalLow_far_field`

Verification

All 262 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3869-job dependency-aware build with remote project artifact reuse

disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1209 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 264 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_196_UniformL1Maximum.md`

Checkpoint 196: A genuine countable l1-to-linfinity maximal construction

Constructs the actual countable pointwise supremum of a uniformly bounded family of l1-to-linfinity operators, proves boundedness and nonnegativity, realizes it in real linfinity, and proves its norm bound. A fresh full rebuild is performed.

Checked declarations

Module	Named supporting theorems
UniformL1Maximum.lean	4

- `operatorL1Maximum_norm`

<!-- checkpoint-verification -->

Verification

All 263 project modules and the root were freshly rebuilt: 3870 jobs pass without warnings/errors. All 1213 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 265 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_197_PhysicalLowMaximum.md`

Checkpoint 197: The all-scale physical low maximal bound

Applies the countable maximal construction to the genuine physical low kernels at arbitrary scales N>=N0. The conductor, quadratic character, beta and contributing denominator set may all vary with the scale. The result is a true all-input l1-to-linfinity maximal bound; source Fourier correspondence is still separate.

All 278 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3885-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1242 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 280 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_212_IntegerRationalPhase.md`

Checkpoint 212: Exact agreement with the rational additive character

Exact agreement with the rational additive character. This module proves the stated construction or operator consequence for genuine continuous circle symbols, with the actual Gauss/twisted coefficients and the source annular smoothing. The parameter domain is natural N,Q>=2 with 2Q<=N^2, positive conductor, a quadratic character, beta<=1 and the explicit contributing-denominator width conditions. No analytic low estimate is assumed. The exact identification with the earlier rational-indexed circle approximation model, general real cutoffs, the sharp high estimates and Theorem 1.1 remain separate obligations. The Lean declarations specify every condition and normalization.

All 293 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3900-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1271 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 295 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_227_L2SquareEnergy.md

Checkpoint 227: Exact square energy of an integer l2 sequence

Exact square energy of an integer l2 sequence. This module proves the exact finite or infinite statement in its Lean declarations with no proof placeholder and no added mathematical axiom. The square-function construction requires summability of squared output norms, rather than the stronger sum-of-norms hypothesis used in the earlier envelope argument. The symbol criterion is a proved implication from explicit frequency square bounds; it is not a claim that the paper's complete high or multifrequency estimate has

already been established. The source annular collar stages retain beta in [0,1], the exact rational-scale onset and all dyadic powers. Theorem 1.1 remains open.

Verification

All 308 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3915-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1308 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 310 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_242_DyadicAnnularFrequencyDecay.md`

Checkpoint 242: Geometric decay after an actual annular collar onset

Geometric decay after an actual annular collar onset. This module proves the exact finite or infinite statement in its Lean declarations with no proof placeholder and no added mathematical axiom. The square-function construction requires summability of squared output norms, rather than the stronger sum-of-norms hypothesis used in the earlier envelope argument. The symbol criterion is a proved implication from explicit frequency square bounds; it is not a claim that the paper's complete high or multifrequency estimate has already been established. No own-paper analytic conclusion is assumed.

`Checkpoint_247_RationalNumeratorUnits.md`

Checkpoint 247: Canonical rational numerators as actual residue units

The canonical numerator of every reduced rational determines an actual unit modulo its positive reduced denominator. For a center in the finite canonical set, the least nonnegative representative of that unit is exactly the natural numerator. The proof uses the rational's proved coprimality and its canonical interval bounds; no new indexing equivalence is assumed. The denominator-one center zero is included. This is the first direction of the required rational/unit correspondence. The complete low-model correspondence and high-frequency estimates remain open at this stage.

No own-paper analytic conclusion is assumed.

`Checkpoint_248_UnitRationalReduction.md`

Checkpoint 248: Exact reduced numerator and denominator of a unit fraction

A unit modulo positive q defines the rational val(u)/q. Its numerator and denominator are proved to be val(u) and q, using the unit's coprimality and the exact reduced-fraction theorems. In particular no denominator can silently drop during reindexing. Modulus one remains in the domain. These statements supply the converse arithmetic direction of the rational/unit bridge, with no analytic hypothesis.

All 324 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3931-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1341 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 326 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_258_UnitRationalSourceCoordinates.md`

Checkpoint 258: Exact source frequency and numerator coordinates

Exact source frequency and numerator coordinates. These are actual rational and Dirichlet-character constructions, not substitute functions with assumed estimates. Both absence and presence of an exceptional character are represented. Existence of analytic exceptional data is a separate external input and is not asserted. The source correspondence retains every phase and normalization.

Checkpoint 274: The logarithmic ordinary kernel decay with the actual real cutoff

The logarithmic ordinary kernel decay with the actual real cutoff. For N>=2 and real Q>=2 the actual ordinary inverse kernel is bounded by an absolute constant times Q log(2Q)/N^2 times the tenth-order spatial decay profile. Integer denominators are enumerated by floor(Q); Q is retained unchanged in the smoothing widths. The arithmetic logarithmic estimate is already proved without PNT or Mertens. The exceptional and source assemblies are separate obligations.

Verification

All 341 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3948-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1374 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 343 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_275_RealLowAmplitude.md

Checkpoint 275: Uniform real-cutoff amplitudes and scale monotonicity

Uniform real-cutoff amplitudes and scale monotonicity. For N>=2 and real Q>=2 the actual ordinary inverse kernel is bounded by an absolute constant times Q log(2Q)/N^2 times the tenth-order spatial decay profile. Integer denominators are enumerated by floor(Q); Q is retained unchanged in the smoothing widths. The arithmetic logarithmic estimate is already proved without PNT or Mertens. The exceptional and source assemblies are separate obligations.

The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_290_ExceptionalCenteredLow.md`

Checkpoint 290: The actual induced exceptional centered cutoff symbol

The actual induced exceptional centered cutoff symbol. The conductor is positive, all quotient denominators are genuine natural quotients of multiples, and the exact real cutoff is retained. The set records both B0*d<=Q and q0*d<=floor(R), including their equality boundaries. B0 is the previously proved conductor majorant. No replacement of an arithmetic or source identity by a hypothesis is made.

`Checkpoint_306_RealCombinedLowKernel.md`

Checkpoint 306: The actual combined real-cutoff low symbol and its inverse kernel

The actual combined real-cutoff low symbol and its inverse kernel. Ordinary and optional induced exceptional kernels are combined with the exact subtraction sign. For N>=2, real Q>=2, a quadratic

base character, beta<=1 and 2Q<=N^2, the kernel has a uniform 2*C_low*Q*log(2Q)/N^2 rapid-decay bound, and the finite local estimate has constant 8*C_low*Q*log(2Q). The l1-to-linfinity operator estimate holds for all l1 inputs and is uniform in the global denominator truncation. No deep analytic input is used.

<!-- checkpoint-verification -->

Verification

All 373 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 3980-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1429 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 375 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_307_RealCombinedLowBounds.md`

Checkpoint 307: The complete real-cutoff low decay and l1 operator bounds

The complete real-cutoff low decay and l1 operator bounds. Ordinary and optional induced exceptional kernels are combined with the exact subtraction sign. For N>=2, real Q>=2, a quadratic base character, beta<=1 and 2Q<=N^2, the kernel has a uniform 2*C_low*Q*log(2Q)/N^2 rapid-decay bound, and the finite local estimate has constant 8*C_low*Q*log(2Q). The l1-to-linfinity operator estimate holds for all l1 inputs and is uniform in the global denominator truncation. No deep analytic input is used.

Checkpoint_309_SourceLowFamilies.md

Checkpoint 309: Actual source low families and their genuine countable l1 maximum

Actual source low families and their genuine countable l1 maximum. The source data structure contains only numerical, character and cutoff compatibility conditions, never the desired norm conclusion. Its circle symbol is the original rational-indexed low model with optional induced exceptional data. The proved all-input l1 bound gives a genuine countable maximum, allowing varying conductor, character, beta and radius at later scales. Source range conversion keeps the global denominator cap fixed while enlarging only the working geometry.

conclusion is assumed.

`Checkpoint_321_AnnularHighFactor.md`

Checkpoint 321: Uniform size and effective-cutoff decay of the actual annular high factor

Uniform size and effective-cutoff decay of the actual annular high factor. These are proved arithmetic and annular estimates for the actual source components. Gauss decay is available at every exponent delta<1/2, and the selected conductor majorant divided by its level has one absolute bound. The annular high mask is zero on the narrow core and its nonzero onset forces the displayed decay. These are steps toward a genuine single-scale high operator estimate; no full high maximal or multifrequency conclusion is assumed.

Verification

All 388 project modules and the root were freshly rebuilt: 3995 jobs pass without warnings/errors. All 1467 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 390 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_322_HighFactorInterpolation.md`

Checkpoint 322: Fractional-power interpolation of the actual high size and tail bounds

Fractional-power interpolation of the actual high size and tail bounds. The original centered high symbol is retained. The effective exceptional cutoff is Q*q0/B0, and the source quotient condition and smoothing width are proved algebraically identical to that cutoff. Interpolation of the proved size and decay bounds gives a genuine fractional Q saving, with the complementary denominator power retained for the coming dyadic sum. No high estimate is assumed.

The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_338_CircleHighL2PowerBound.md`

Checkpoint 338: The actual high l2 multiplier from its proved power symbol bound

The continuous-circle high estimate implies the genuine l2 operator norm bound with the same explicit H(C,T,delta,eta). Positivity of that constant is checked from the strict exponent gap. This is the actual source operator, not an abstract operator supplied with the desired norm as a hypothesis.

Verification

All 405 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4012-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1492 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 407 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_339_SourceHighPowerUniform.md`

Checkpoint 339: An unconditional single-scale high bound at every exponent below one half

For every 0<eta<1/2 there is H_eta>0, independent of N,Q,denominator cap,conductor and character family, such that the actual high circle symbol and its l2 operator are bounded by H_eta Q^(-eta), for N>=2,Q>0,beta in [0,1], canonical finite rational centers and coefficients of norm at most one. The Gauss and conductor bounds are discharged using the proved arithmetic theorems. This is weaker than the sharp printed half-power subexponential bound and does not prove a countable high maximum. The uniform estimate is for the actual defined circleHighModel complement. Identification with the printed high decomposition uses the proved low source bridge and source scale geometry.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_373_DyadicSparseSquareEnergy.md`

Checkpoint 373: Uniform square-energy summation over the actual active rational centers

For one denominator block, actual broad support leaves at most four active canonical centers independent of the dyadic arithmetic index. Summing the individual finite time energies gives a full rational-sum energy at most (4A)^2, with every inactive term exactly zero. The bound is independent of the total number of rational centers.

All 457 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4064-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1570 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 459 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_391_CompleteRationalCollarEnergy.md`

Checkpoint 391: The complete fixed-Q rational collar square-energy bound

For every finite canonical rational set with denominators at most floor Q, coefficients bounded by C den^(-delta), and beta values in [0,1], the actual full collar model has finite time energy at most (collarPowerConstant(C,delta) Q^(-delta))^2. Positive weighted finite energy assembly and the proved real-cutoff geometric budget discharge the complete frequency energy premise.

Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_408_DyadicSourceLogBudget.md`

Checkpoint 408: The actual paper logarithmic cutoff budget persists on every dyadic tail

For c>0 and M>=2, the allowed real-Q logarithmic range at M implies the same range at every dyadic arithmetic scale 2^j M. The source radius at each of those scales also contains Q. All natural-to-real casts and positivity of the logarithmic coefficient are checked.

- `conductor_divides_den_lower`

<!-- checkpoint-verification -->

Verification

All 492 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4099-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1612 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 494 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and

Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_426_ConductorGaussEnvelope.md

Checkpoint 426: A conductor-sensitive actual twisted Gauss envelope

Discharges the arithmetic coefficient premise with the actual uniformly bounded twisted square Gauss sums. The coefficient envelope gains $q_0^{-\varepsilon}$, provided $\eta+\varepsilon<1/2$. Characters need not be principal or fixed across the dyadic scales.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

Checked declarations

Verification

All 493 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4100-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1613 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 495 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_427_CollarConstantLinearity.md

Checkpoint 427: Exact homogeneity of the complete collar constant

Proves the exact homogeneity needed to carry the conductor power through the full denominator-block energy constant, avoiding an unexplained change in the quantitative bound.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

All 509 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4116-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1629 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 511 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_443_LargeCenteredExceptionalHigh.md`

Checkpoint 443: The exact exceptional high term above its effective cutoff

Identifies the remaining large-denominator exceptional high contribution with the full twisted model rather than a collar. No maximal estimate for this piece is claimed.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1646 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 528 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_460_ConductorClassPositivity.md`

Checkpoint 460: Positive conductors from dyadic class lower bounds

Records the precise numerical classification premise used in the changing-character argument: the conductor assigned to class i is at least 2^i. It proves positivity but does not assert a formalized Landau–Page theorem.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

Checked declarations

All 1665 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 545 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_477_ChangingSourceCollarPairing.md`

Checkpoint 477: The original changing-character source collar finite-indicator pairing

Proves the finite-indicator restricted pairing for the actual changing-character source collar maximum. It supplies a checked component of the eventual high restricted estimate, with the large-denominator terms still separate.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

Checked declarations

Module	Named supporting theorems
ChangingSourceCollarPairing.lean	1

<!-- checkpoint-verification -->

Verification

All 546 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4153-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1669 named theorems pass a fresh complete

transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 548 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_480_CommonTailMaskCounterexample.md`

Checkpoint 480: A checked obstruction to treating a denominator prefix as one common tail

Proves a finite exact counterexample to the common-tail mask claim: denominators 2 and 3, in the same dyadic block, have activation rows (1,0) and (1,1) at radii 2 and 3. This concerns a proof step in Proposition 6.21; it is not a counterexample to its conclusion. The appropriate repair is a denominator-prefix maximum, as in the paper's Corollary 6.19.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

Checked declarations

Verification

All 577 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4184-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1710 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 579 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_511_BinaryTreeIntervalDomination.md`

Checkpoint 511: Domination of every scalar binary tree by interval majorants

Proves that interval-wise pointwise majorants dominate the entire scalar binary tree at every time. No positivity premise is needed beyond what follows from domination of norms.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

This checkpoint passes a 4201-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1729 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 596 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

Checkpoint_528_SharpHighPolynomialAbsorption.md

Checkpoint 528: Uniform absorption of fixed powers into the sharp high exponent

Proves uniform absorption of any fixed real polynomial power into an arbitrarily small addition to the sharp high exponent coefficient, including bounded L≥2.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_544_SourceAnnularSymbolFrontier.md`

Checkpoint 544: The exact annular prime-square symbol at the final proof frontier

Provides the exact continuous-symbol form of the final source decomposition, with no analytic error or large-denominator estimate hidden in the statement.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

Checked declarations

Module	Named supporting theorems
SourceAnnularSymbolFrontier.lean	1

- `annularSymbol_source_frontier`

<!-- checkpoint-verification -->

Verification

All 611 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4218-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1746 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 613 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_545_SourcePointwiseConvolutionBound.md`

Checkpoint 545: The unconditional pointwise triangle bound for the exact source decomposition

Proves an unconditional pointwise bound for the actual finite-input prime-square convolution by the four exact source pieces. The statement leaves every still-unbounded piece visible.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

Checked declarations

Module	Named supporting theorems
SourcePointwiseConvolutionBound.lean	1

<!-- checkpoint-verification -->

Verification

All 612 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4219-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1747 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 614 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_546_SourceCollarSubhalfMaximum.md`

Checkpoint 546: The completed subhalf-power source collar maximum with no auxiliary epsilon parameter

Completes the actual signed original source collar maximum for every 0≤η<1/2, eliminating the auxiliary epsilon by an explicit admissible choice. It includes arbitrary source clipping, character activity and changing conductor-class selection subject to the displayed numerical class condition. The genuine real ℓ^2 witness dominates every scale and has norm Kη Q^{-η}‖f‖₂. Theorem 1.1, the sharp full high maximum and the large-denominator remainder remain open.

The claims are exactly the displayed Lean declarations. No new axiom or manuscript conclusion is assumed. The sharp full high maximal bound, Proposition 4.19 and Theorem 1.1 remain open.

The exact interpretation as the complete original source high collar retains Q<=R at every scale. The displayed continuous-symbol bound also covers the explicitly defined extension at smaller nonnegative radii where permitted by its signature. Identification with the printed cutoff-difference formula retains the earlier source geometry and low-symbol bridge.

`Checkpoint_562_PaddedMultiplierEnergy.md`

Checkpoint 562: Binary padding does not enlarge the multiplier square budget

Proves exact equality between the padded budget at any capacity T>=L and the original finite square-energy sum. All extra padded operators are zero, not estimated by a cardinality loss.

Checked declarations

Module	Named supporting theorems
PaddedMultiplierEnergy.lean	1

- `paddedMultiplier_square_budget`

<!-- checkpoint-verification -->

Verification

All 629 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4236-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1766 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 631 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_563_FiniteDisjointPrefixMaximum.md`

Checkpoint 563: Finite disjoint symbol families have a true prefix majorant

Produces one nonnegative real l2 function for every prefix of a finite family. Its norm uses the exact original L-term energy and binary depth h whenever L<=2^h; the support hypothesis is finite.

Checked declarations

Module	Named supporting theorems
FiniteDisjointPrefixMaximum.lean	1

This checkpoint passes a 4254-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1787 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 649 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_581_RationalCircleDenominatorBlocks.md`

Checkpoint 581: Actual rational circle symbols have exact denominator blocks

Defines denominator blocks for an arbitrary rational-indexed continuous circle symbol. The complete finite sum equals the sum of its blocks whenever all denominators are at most M, including the identically empty denominator-zero block.

Checked declarations

Module	Named supporting theorems
RationalCircleDenominatorBlocks.lean	1

- `rationalCircle_full_blocks`

All 1805 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 667 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_599_NoL2UnitMassMajorant.md`

Checkpoint 599: Countably many distinct unit masses have no l2 pointwise majorant

Uses the finite lower bound and the Archimedean property to rule out any real l2 function that is at least one on every nonnegative integer. No numerical sampling or informal divergence argument substitutes for the proof.

Checked declarations

Module	Named supporting theorems
NoL2UnitMassMajorant.lean	1

Verification

All 666 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4273-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1806 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 668 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_600_UniformMultiplierNormCounterexample.md`

Checkpoint 600: Uniform single-scale multiplier bounds do not imply a countable maximal bound

Closes this milestone with an explicit counterexample using the actual continuous circle symbols and existing integer Fourier multipliers: every character multiplier has operator norm at most one, yet their outputs on the unit mass at zero have no real l2 pointwise majorant. This proves why the remaining full

high maximum needs a separate argument. The counterexample concerns a general family, not a counterexample to the manuscript theorem. Theorem 1.1, Proposition 4.19 and the source multifrequency interval estimate remain open.

Checked declarations

Verification

All 684 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4291-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1824 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 686 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_618_CircleRationalModelSupport.md`

Checkpoint 618: Actual rational circle models are supported in their actual source cutoffs

Establishes support containment of the complete rational model, including exceptional terms, in the genuine circle source cutoff. The denominator scale is its actual floor binary logarithm.

Checked declarations

Module	Named supporting theorems
CircleRationalModelSupport.lean	1

- `circleRationalModel_cutoff_nonzero`

This checkpoint passes a 4309-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1843 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 704 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and

Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_636_InitialTemporalMaximumL2.md`

Checkpoint 636: Every finite time maximum is an actual l2 vector

Under the displayed finite-maximal hypothesis, proves membership of the exact finite pointwise maximum in real l2 by domination. This provides genuine finite maximum vectors, rather than formal supremum notation alone.

Checked declarations

Module	Named supporting theorems
InitialTemporalMaximumL2.lean	1

<!-- checkpoint-verification -->

Verification

All 721 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4328-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1862 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 723 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic

conclusion is assumed.

Checkpoint_655_AnnularProjectionErrorProfile.md

Checkpoint 655: One explicit constant controls both projection-error regimes

Packages the actual annular projection error with uniform linear and reciprocal bounds and a positive explicit constant. These are the hypotheses of the next telescoping square-energy argument.

Checked declarations

Module	Named supporting theorems
AnnularProjectionErrorProfile.lean	1

- `annularProjectionError_profile`

<!-- checkpoint-verification -->

Verification

All 722 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4329-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1863 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 724 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_691_RationalGaussSmoothMainBlock.md`

Checkpoint 691: The original finite rational model has an exact smooth-main and error-block decomposition

Defines the actual smooth main block and proves its exact relation to the original circleMajorArcModel on one denominator scale. Both the ordinary and exceptional error blocks are the actual controlled symbols constructed earlier.

Checked declarations

Module	Named supporting theorems
RationalGaussSmoothMainBlock.lean	1

- `circleMajorArcModel_smooth_error_blocks`

No own-paper analytic conclusion is assumed.

`Checkpoint_700_SourceBlockReductionToSmoothMaximum.md`

Checkpoint 700: The actual source block maximum reduces to the smooth finite-family estimate

Combines the proved uniform finite-family to countable maximal extension with the fully discharged annular comparison-error maximum. On an actual dyadic rational block, a supplied smooth-main finite-family maximal bound B yields a genuine countable source-block majorant with norm at most (B+2 C_error) times the input norm. The smooth-main premise remains explicit and unproved here. This is a reduction; it does not complete Lemma 6.16, Proposition 6.21, Proposition 4.19 or Theorem 1.1. This draft was reconstructed after recovering the confirmed checkpoint699 archive and is counted complete only after its new production build, full audits and save.

Checked declarations

All 775 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4382-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1922 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 777 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. Published Ren and Ghosh quadratic exponential-sum estimates, when consumed, remain displayed raw theorem hypotheses; the progression-prefix estimate also remains an explicit unproved input. No own-paper analytic conclusion is assumed.

`Checkpoint_709_SmoothCutoffSourceLiftCompatibility.md`

Checkpoint 709: The general narrow cutoff and broad source cutoff use the same integer lift

The general narrow cutoff and broad source cutoff use the same integer lift. Reconstructed after recovering the confirmed checkpoint699 project. This is a supporting source/smooth-cutoff statement; it does not prove the smooth maximal theorem or Theorem1.1. Counted complete only after individual production compilation, full audits and separate save.

- `largeStart_actualSource_maximum`

<!-- checkpoint-verification -->

Verification

All 792 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4399-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1944 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 794 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The raw progression-prefix and published Ren/Ghosh estimates remain explicit unproved hypotheses. SmoothCircleBourgainInput is a newly explicit compound unproved external analytic boundary, comprising the general smooth multifrequency estimate, sampling, normalization and fixed bump. Its existence is not proved. The Lean theorems prove implications conditional on it; the axiom audit does not certify this hypothesis. No own-paper annular lemma is assumed.

`Checkpoint_726_WeightedAnnularLargeStartMaximum.md`

Checkpoint 726: A general weighted annular block has a conditional large-start countable maximum

Defines the actual weighted bare annular source block with fixed rational centers and coefficients, proves its exact smooth-plus-error decomposition, and derives a genuine countable real-l2 majorant conditional on SmoothCircleBourgainInput C. The bound is A*(C*circleFrequencyLogFactor/2+E) times the input norm. Beta may vary with time in [0,1]. Both large-start inequalities and s>=2 remain explicit. No new external hypothesis is introduced. Arbitrary starting scales, small source scales, denominator/conductor summation and the printed stronger multifrequency claims remain open. The paper-level checklist is saved and its 54-claim coverage is refreshed with every subsequent checkpoint; this supporting unit closes no new whole paper statement.

Verification

All 793 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4400-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1946 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 795 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains

two earlier explicit PNT limits; its external bridge is not integrated or used here. The raw progression-prefix and published Ren/Ghosh estimates remain explicit unproved hypotheses. SmoothCircleBourgain-Input is a newly explicit compound unproved external analytic boundary, comprising the general smooth multifrequency estimate, sampling, normalization and fixed bump. Its existence is not proved. The Lean theorems prove implications conditional on it; the axiom audit does not certify this hypothesis. No own-paper annular lemma is assumed.

`Checkpoint_727_PrimeFactorThresholdBudget.md`

Checkpoint 727: A common prime-factor threshold controls every conductor product

Proves an arbitrary fixed-threshold reciprocal prime-factor budget and the corresponding bound for the logarithm of the actual conductorRho product, uniformly for every positive modulus including small moduli. The resulting exponential envelope is centered at a common threshold y and has the explicit slope gaussThresholdSlope y. These elementary statements use no PNT input; PNT will later identify the sharp leading constant of the envelope at y=log Q. This is the first arithmetic step on the fixed-scale route to Theorem1.1, which does not require the full countable high maximum. No whole source statement is newly closed.

Verification

All 794 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4401-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1951 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 796 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. The raw progression-prefix and published Ren/Ghosh estimates remain explicit unproved hypotheses. SmoothCircleBourgain-Input is a newly explicit compound unproved external analytic boundary, comprising the general smooth multifrequency estimate, sampling, normalization and fixed bump. Its existence is not proved. The Lean theorems prove implications conditional on it; the axiom audit does not certify this hypothesis. No own-paper annular lemma is assumed.

`Checkpoint_728_ThresholdEnvelopeBounds.md`

Checkpoint 728: Sharp threshold envelopes on both sides of the denominator cutoff

Proves that the common-threshold slope tends to zero and is eventually at most one quarter. Under the existing two PNT inputs, the threshold exponent divided by the source regularized Orlicz weight tends to2, with its full epsilon consequence. The actual conductorRho product is bounded uniformly below the threshold and with a quarter-power relative loss above it. These are the arithmetic envelopes required for the fixed-scale high bound; no source high estimate or Theorem1.1 conclusion is assumed.

SmoothCircleBourgainInput is a newly explicit compound unproved external analytic boundary, comprising the general smooth multifrequency estimate, sampling, normalization and fixed bump. Its existence is not proved. The Lean theorems prove implications conditional on it; the axiom audit does not certify this hypothesis. No own-paper annular lemma is assumed.

`Checkpoint_729_RationalRelativeCutoffSum.md`

Checkpoint 729: Uniform rational sums with two relative denominator cutoffs

Proves a denominator-relative cutoff profile and bounds a genuine finite rational-frequency sum by its dyadic profile, including all small dyadic scales. Reuses the already proved uniform interpolation-weight sum to obtain a two-cutoff bound independent of the ordinary and exceptional positive cutoff locations. This provides the geometric summation needed for the sharp fixed-scale high symbol; no multifrequency maximal input, PNT, or own-paper high estimate is assumed.

Its existence is not proved. The Lean theorems prove implications conditional on it; the axiom audit does not certify this hypothesis. No own-paper annular lemma is assumed.

`Checkpoint_733_SourceHighThresholdUniform.md`

Checkpoint 733: Uniform sharp-envelope fixed-scale high operator

Combines the checked ordinary and induced-character profiles with rational-frequency sparsity, uniform two-cutoff geometric summation, and the exact three-term periodization formula. Proves a uniform bound for the actual circle high model and its actual l2 operator, with Q^{-1/2} times the explicit Gauss majorant. The constant is uniform in the arithmetic scale, conductor, quadratic character, selector, cutoff and canonical finite rational set. The bound is unconditional when the explicit threshold-slope conditions hold. Theorem 1.1 remains the assembly target.

Its existence is not proved. The Lean theorems prove implications conditional on it; the axiom audit does not certify this hypothesis. No own-paper annular lemma is assumed.

`Checkpoint_734_SourceHighOrliczUniform.md`

Checkpoint 734: Sharp fixed-scale high bound with every coefficient above two

Proves the actual fixed-scale high-model and high-operator bounds with Q^{-1/2} times exp(c1*sqrt(log Q)/log(log Q)) for every c1>2, under the existing precise PNT limits. The estimate is uniform at every dyadic cutoff Q>=2. The cutoff Q=2 is treated separately, since the unregularized log-log denominator prevents a uniform compact comparison across Q=e. Larger cutoffs use the checked common-threshold envelope, with the weaker unconditional high bound absorbing the finite range. No maximal estimate is claimed. This closes the sharp fixed-scale high bound needed for Theorem 1.1, while its final operator and interval assembly remains open.

Its existence is not proved. The Lean theorems prove implications conditional on it; the axiom audit does not certify this hypothesis. No own-paper annular lemma is assumed.

`Checkpoint_735_IndependentSquareDecomposition.md`

Checkpoint 735: Independent square input and checked full-to-annular transfer

Introduces a precise, explicitly unproved external interface for the independent full unweighted-square decomposition. Its global norm form is a compound consequence of Han–Lacey–Yang's published Fourier construction and local estimate, including reflection; it is not claimed to have been imported from Mathlib. Proves the actual full-to-annular identity on finite indicators and deduces the annular high/low operator bounds at even cutoffs, with the spatial-scale and one-half factors checked in Lean. No prime-square conclusion is an assumption of this interface. Theorem 1.1 remains open pending assembly.

Verification

All 806 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4413-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1991 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 808 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. See docs/THEOREM_1_1_EXTERNAL_INPUTS.md. PNT limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_740_OrliczScaleComparison.md`

Checkpoint 740: Exact Orlicz loss under bounded changes of density

Proves the bounded-additive-shift estimate for the exact square-root Orlicz weight and the resulting multiplicative comparison for Phi when two densities differ by at most a fixed factor. The endpoint coefficient is preserved exactly; the fixed factor only changes the outside constant. This is needed for the dyadic-to-arbitrary arithmetic cutoff and source interval normalization in Theorem 1.1. No new analytic input is used.

Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. See docs/THEOREM_1_1_EXTERNAL_INPUTS.md. PNT limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_741_DyadicEndpointReconstruction.md`

Checkpoint 741: Exact full-average pairing and endpoint rescaling

Proves exact reconstruction of the genuine full von-Mangoldt kernel pairing from descending dyadic annuli, using the already checked identity of actual continuous operators. Proves the exact change of finite-set density between two square spatial scales and the two-thirds endpoint scaling identity, including all normalization factors. These are equalities, not numerical checks or new analytic assumptions, and are used in summing the annular endpoint to the full average.

Checked declarations

Verification

All 808 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4415-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 1996 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 810 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. The abstract results retain their source hypotheses. Full Lemma 6.5, Proposition 4.19 and headline applications remain open. Lemma 3.21 retains two earlier explicit PNT limits; its external bridge is not integrated or used here. See docs/THEOREM_1_1_EXTERNAL_INPUTS.md. PNT limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_742_PrimeSquareFullDyadicEndpoint.md`

Checkpoint 742: Sharp full-average endpoint at every dyadic cutoff

Proves the sharp restricted endpoint for the genuine FULL von-Mangoldt square average at every dyadic arithmetic cutoff. The proof uses the exact descending-annulus pairing identity, extends each annular bound to density above one with the actual Chebyshev l2 estimate, preserves the paper Phi by density

monotonicity, and sums the resulting one-third-power geometric weights. Every rescaling factor and the uniform geometric constant are checked in Lean. This completes the full dyadic endpoint, conditional on the already recorded independent deep inputs; arbitrary arithmetic cutoffs, interval normalization and strong interpolation remain.

limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_750_WeightedAnnularBlockBounds.md`

Checkpoint 750: Bound each actual annular block uniformly at the initial scales

The actual annular source on the circle has a uniform pointwise bound. Its support lies inside the source cutoff, and distinct canonical centers in one sufficiently separated denominator block give disjoint supports. Consequently a fixed weighted annular block, with coefficients bounded by A, has multiplier operator norm at most (3/2)A, uniformly in the starting scale. These are bounds for the actual periodized oscillatory-integral symbols. They supply the finite initial-scale part of the maximal argument; they do not assert Proposition 6.21.

PNT limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_751_WeightedAnnularAllStartingScales.md`

Checkpoint 751: Complete the weighted annular maximum from every starting scale

The weighted annular-source maximum now holds from every starting scale M >= 2, under the existing general smooth multifrequency input. The proof chooses an explicit later starting scale 2^(2s+3) M at which both separation budgets hold, applies the previously checked infinite-tail result there, and adds the finitely many earlier operators using their actual uniform norm bound. The resulting loss is A times [(3/2)(2s+3)+(C/2)(1+log(card Gamma+1))^2+E]. No maximum, initial segment, or scale range is assumed as an extra input. The fixed polynomial logarithmic loss is compatible with the o(1) in Proposition 6.21; the stronger printed auxiliary logarithmic exponent is not claimed.

`Checkpoint_752_NestedSourceLocalization.md`

Checkpoint 752: Localize actual annular sources with disjoint wider cutoffs

The actual circle source is localized by a wider cutoff: the wider cutoff equals one everywhere that the original cutoff is nonzero. The proof passes through the unique real lift, with the actual smooth bump's core radius 1/2 and support radius 1. A general denominator-separation statement proves disjointness of the wider cutoffs. For denominator blocks s >= 4, the cutoff at s-1 is both sufficiently wide to localize the source at s and sufficiently narrow to remain disjoint between distinct canonical centers. These facts will let the time-and-denominator maximum use orthogonal filtered inputs rather than pay for the number of denominators.

explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

Checkpoint_753_FiniteFrequencyTruncationMaximum.md

Checkpoint 753: Control time and denominator truncations using localized input energy

A general finite-frequency theorem now controls the maximum jointly over time and every real denominator cutoff. Its hypotheses are localization by pairwise disjoint cutoff symbols of norm at most one and a hereditary time-maximal estimate on each frequency subset. The proof groups the frequencies by denominator, constructs each interval majorant on the corresponding filtered input, applies the already proved time-dependent Rademacher-Menshov inequality, and uses multiplier Bessel orthogonality to recover the original input norm. The final loss is h+1 when the maximum denominator plus one is at most 2^h. In particular, it does not introduce a square-root loss in the number of denominators. This is a proved abstract transfer theorem, with the actual source-family instantiation still to follow.

Verification

All 820 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4427-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2037 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 822 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results under their paper hypotheses remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. In addition, Lemma 3.21 and BOTH conclusions of Theorem 1.1 are complete checked implications under their explicit independent deep inputs. The PNT limits are used in the sharp Gauss/high bound; an imported PNT bridge is not integrated. The whole paper, the full maximal clauses of Proposition 4.19/6.21 and the later headline applications remain unfinished. See docs/THEOREM_1_1_EXTERNAL_INPUTS.md. PNT limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

Checkpoint_754_AnnularBlockLogarithmicBudget.md

Checkpoint 754: Bound the actual frequency and truncation losses by a cubic logarithm

The frequency-cardinality loss is now bounded by the denominator-block index: (1+log(card Gamma+1))^2 <= 36(s+1)^2 for canonical centers of denominator at most 2^(s+1). The proof uses the actual finite enumeration bound, not an asymptotic cardinality assumption. Combining this with the finite initial-scale loss and the denominator-truncation factor gives an explicit constant K(C)=3(8+18C+E) multiplying A(s+1)^3. This fixed cubic logarithmic cost is harmless in the final sharp-exponent asymptotic, but no sharper auxiliary logarithmic exponent is asserted.

`Checkpoint_755_WeightedAnnularTruncationMaximum.md`

Checkpoint 755: Complete the actual annular maximum with changing denominator cutoffs

The actual weighted annular-source block now has a proved joint maximum over every dyadic scale from M >= 2 and every real upper denominator cutoff. For s >= 4 and coefficients bounded by A, the majorant has l2 norm at most K(C) A(s+1)^3 times the input norm. Its only analytic boundary is the previously explicit general smooth multifrequency input. The proof constructs disjoint wider source cutoffs, localizes the actual symbols, derives the hereditary time estimate from the all-starting-scale theorem, and applies the checked denominator-truncation theorem and cardinality budget. This supplies the formerly missing actual-source interval estimate without assuming a maximal statement from this paper.

limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

Checkpoint_756_PolynomialDyadicProfileSum.md

Checkpoint 756: Sum polynomially weighted sharp cutoff profiles uniformly

For every positive decay exponent and every fixed polynomial degree, the two-sided dyadic cutoff profile is summable even after multiplication by (s+1)^m. Its total is bounded uniformly by an explicit constant times (1+log W)^m for W >= 1. The proof splits at a genuine dyadic scale adjacent to W, uses the previously verified uniform profile sum for the lower part, and sums a polynomial times a geometric sequence for the upper part. This provides the sharp arithmetic summation needed after the cubic logarithmic block loss, without weakening the Q^(-1/2) leading power.

Checkpoint_757_ThresholdCoefficientAmplitudes.md

Checkpoint 757: Extract sharp conductor-sensitive amplitudes on both sides of the cutoff

The common-threshold Gauss-product envelope now gives separate, exact coefficient bounds on both sides of an effective cutoff. After extracting A sqrt(B) Q^(-1/2) exp(G(log Q)), the small-denominator coefficient is bounded by t^(-1/2), and the large-denominator coefficient by t^(-1/4). These imply uniform amplitudes on each dyadic denominator block. Two elementary profile inequalities convert the actual collar gain and the large-block maximum into the same two-sided profile of exponent 1/4. The argument preserves the conductor factor rather than replacing it by a worse denominator estimate.

`Checkpoint_758_ThresholdAnnularSource.md`

Checkpoint 758: Identify the actual high operator with the common threshold-annular family

The ordinary and exceptional pieces of the actual high symbol are identified exactly with a common threshold-annular family. Below the effective cutoff this family is the actual narrow-cutoff collar; above it the family is the actual broad annular source. This identity is proved for each source term and for the full finite high model, with the exceptional effective threshold Q q_chi/B_chi. A separate exact identity writes an arbitrary varying upper denominator cutoff in a collar block as a time-dependent coefficient bounded by the original coefficient. No maximal estimate is built into these definitions.

Checkpoint_759_SharpAnnularBlockMaximum.md

Checkpoint 759: Prove sharp maximal bounds for both actual high-block pieces

Both actual pieces of a dyadic high block now have sharp maximal majorants. The collar proof allows arbitrary changing upper denominator cutoffs by masking its coefficients and uses the already proved square-function estimate. The large-denominator proof uses the actual joint scale-and-cutoff maximum, not a scalar symbol norm. After extracting the common amplitude A sqrt(B) Q^(-1/2) exp(G(log Q)), both bounds have the same two-sided relative-cutoff profile; the large piece also has the verified cubic logarithmic factor. An effective cutoff at least 16 ensures that every nonempty large block satisfies the separation index required by the source theorem. Empty blocks and all smaller collar blocks are explicitly handled.

Checkpoint_760_SharpThresholdFiniteMaximum.md

Checkpoint 760: Assemble and sum the full sharp high maximum over finite center sets

The collar and large-denominator majorants are now assembled for the exact threshold-annular high family. Summing over every dyadic denominator block gives a uniform maximal bound K(C) A sqrt(B) Q^(-1/2) exp(G(log Q)) (1+log W)^3. This theorem allows any finite canonical center set, has a constant independent of that set's maximum denominator, starts at every M >= 2, and allows an arbitrary nonnegative sequence of real denominator cutoffs. The proof uses actual continuous multipliers and lp majorants throughout. No fixed-scale symbol estimate is substituted for a maximal estimate.

`Checkpoint_761_SharpThresholdCountableMaximum.md`

Checkpoint 761: Complete the sharp maximum for an unbounded changing denominator radius

The finite-center sharp estimate now extends to the actual countable family whose maximum denominator changes without bound as the dyadic scale increases. For each finite set of times, the proof forms a common finite center set from the largest actual denominator radius, applies the uniform finite-center theorem, and checks the exact set identity at every selected time. The established finite-to-countable maximal criterion then gives the full countable maximum. The coefficient/support hypotheses concern individual arithmetic coefficients, and no source maximal conclusion is assumed.

`Checkpoint_763_ConductorLogarithmicAbsorption.md`

Checkpoint 763: Retain summable conductor decay after absorbing all logarithmic losses

Every fixed logarithmic power is bounded uniformly by an arbitrarily small positive power of its argument. Applying this to the previously proved conductor decay absorbs (1+log q_chi)^3 while retaining q_chi^(-1/50). The effective-cutoff logarithm separates into a Q logarithm and a conductor logarithm. A separate unconditional arithmetic bound gives a fixed Q threshold above which every exceptional effective cutoff is at least 16. Finally, the retained conductor decay is summable even linearly over a family with at most one character in each dyadic conductor class. These results introduce no external input.

`Checkpoint_765_SharpChangingCharacterMaximum.md`

Checkpoint 765: Complete the actual high maximum for changing class-indexed exceptional characters

The full actual high operator now has a countable dyadic maximal majorant for a class-indexed family of fixed quadratic characters, allowing arbitrary character changes between times, arbitrary active/inactive selectors, and arbitrary beta and denominator-radius sequences in their stated ranges. The only class condition is 2^i <= q_i. The proof uses the exact ordinary-minus-exceptional symbol identity, the sharp ordinary majorant, each fixed-character majorant, and the retained summable conductor decay. Linear summation over occupied classes already converges, so no unproved class square-function estimate is needed. The Q rate remains Q^(-1/2) exp(G(log Q)) (1+log Q)^3, uniformly over starting scales. The next step proves the class parametrization from a precise independent Page input rather than assuming it for the source family.

`Checkpoint_766_RawPageUniqueness.md`

Checkpoint 766: Derive dyadic exceptional-character uniqueness from the raw Landau-Page input

The independent Landau-Page input is now stated precisely for primitive nonprincipal quadratic characters and their real zeros. A zero below 1 is represented by the limit of ordinary Dirichlet-series partial sums, not by an unconditional tsum; the analytic-continuation bridge is explicitly part of the unformalized input. The standard uniqueness region itself remains an explicit general hypothesis, with no operator conclusion assumed. From it, Lean proves uniqueness of the complete character-and-zero datum in each dyadic conductor class after halving the region constant, and proves that source-region eligibility implies conductor-region eligibility. The standard input is documented against Philippe Michel's 2006 lectures, section 1.2 (Landau/Page), https://www.epfl.ch/labs/tan/wp-content/uploads/2018/10/Parkcitylectures.pdf. This does not change Theorem 1.1's previously recorded inputs.

`Checkpoint_767_PageConductorClassSelection.md`

Checkpoint 767: Construct and verify the actual exceptional-character classes from Page uniqueness

The class parametrization is now proved from raw Page uniqueness. The construction chooses an occurring exceptional datum for each occupied dyadic conductor class and supplies a harmless principal-character fallback for empty classes. Lean proves that every active source datum equals its selected representative, that the representative conductor is at least 2^i, and that each selected character is quadratic. Source-region zero data imply the exact conductor-region eligibility used in the uniqueness proof. The selection includes the actual character and zero, not merely the conductor; no unverified identification is made when the exceptional character changes with scale.

Checkpoint_768_ActualPageHighMaximum.md

Checkpoint 768: Complete the sharp maximum for the actual changing exceptional data

The sharp countable maximum is now proved for the actual scale-varying exceptional data. Each active datum contains the primitive real character, conductor, and zero; inactive data give the ordinary family exactly. Page uniqueness proves that the conductor-class map is injective on every finite set of occurring data. The proof sums majorants for those actual data and then passes to the countable maximum, avoiding any unverified change of character or dependent modulus. The resulting Q rate and constant are uniform in the starting scale and changing denominator radius. Page uniqueness, the general smooth multifrequency input, and the already recorded arithmetic inputs remain explicit; no own-paper operator estimate is assumed.

Checkpoint_769_SharpHighMaximalAsymptotic.md

Checkpoint 769: Recover the precise leading-two asymptotic after all maximal losses

The analytic Q rate is converted to the precise leading-two asymptotic. Under the two explicit prime asymptotic inputs, for every epsilon > 0 there are fixed positive constants and a lower Q cutoff such that Q^(-1/2) exp(G(log Q)) (1+log Q)^3 is bounded by a constant times Q^(-1/2) exp((2+epsilon) sqrt(log Q)/log log Q). The same cutoff ensures all threshold-slope conditions needed by the maximal proof. The constants are independent of the starting scale, source radius, and exceptional data. This step does not claim the separate bounded-Q completion.

`Checkpoint_770_Proposition621Asymptotic.md`

Checkpoint 770: Prove the actual source supremum with the sharp asymptotic uniformly in the starting threshold

The actual maximal conclusion of Proposition 6.21 is now proved in precise large-Q epsilon form, uniformly in the real starting threshold N0 >= 2. The multiplier uses the actual source radius R(M)=max(exp((log M)^(1/10)),Q^8), and the source zero-region hypotheses imply the exact Page eligibility used in the proof. Earlier dyadic times are excluded explicitly, and inactive exceptional data require no zero assumption. The resulting real lp function equals the pointwise countable supremum of the actual high outputs; it is not merely an unspecified majorant. Its norm has the sharp Q^(-1/2) exp((2+epsilon) sqrt(log Q)/log log Q) bound, and every individual output has the same bound. The constant and Q cutoff are independent of N0 and all compatible source data. The separate bounded-Q completion remains the next obligation before recording the full source proposition as complete.

`Checkpoint_771_SmallSourceCutoffDifference.md`

Checkpoint 771: Control small denominator indices by a summable actual-cutoff difference

The small denominator indices are compared with the separated cutoff at index 4. The difference vanishes in the common central core and has actual multiplier norm at most an explicit constant divided by N^2, uniformly in beta in [0,1]. The proof uses the true source bump core, oscillatory-integral decay outside that core, and the finite circle-periodization norm bound. This summable error supplies a uniform treatment of the finitely many small denominator indices needed for the bounded-Q completion.

`Checkpoint_772_AllIndexAnnularTruncationMaximum.md`

Checkpoint 772: Complete the actual annular maximum at every denominator index

The actual annular joint scale-and-denominator-cutoff maximum is now proved for every denominator index, including 0, 1, 2 and 3. The small indices use the verified cutoff comparison, a geometric error

maximum, and the separated index-4 source estimate. A concrete finite cardinality bound controls the small center sets. Together with the previously proved large-index maximum, this yields one constant times A(s+1)^3 for every index, every starting M >= 2, every allowed beta sequence, and every nonnegative changing denominator radius. This closes the small-frequency issue required to prove a uniform bounded-Q high maximum.

`Checkpoint_773_PowerDecayingAnnularMaximum.md`

Checkpoint 773: Prove a uniform maximum for the full power-decaying annular family

The full bare annular family with denominator-dependent source indices now has a countable dyadic maximum whenever its fixed coefficients decay by any positive denominator power. The proof uses the all-index joint truncation estimate, the actual dyadic denominator partition, a convergent polynomial-geometric sum, and the verified finite-to-countable passage for the growing source radius. Any fixed lower-denominator restriction or conductor-multiple restriction may be included in the center set. The bound is uniform in the restriction, scale, and changing upper radius. This is the large-denominator input for the bounded-Q high estimate.

Checkpoint_774_PowerThresholdUniformMaximum.md

Checkpoint 774: Prove the uniform threshold maximum needed for bounded Q

The full threshold-annular maximum now has a uniform bound whenever the effective cutoff has any fixed positive lower bound and the arithmetic coefficients have a fixed positive denominator-power decay. The collar part is proved directly from the complete collar square-function estimate, including the empty cutoff range below one; the large part uses the full annular maximum at every denominator index. Every upper source-radius cutoff may vary with time. The result is independent of the size of the effective cutoff above its lower bound. This supplies the separate bounded-Q estimate rather than assuming that it can be absorbed.

Checkpoint_775_UniformPageHighMaximum.md

Checkpoint 775: Complete the actual high maximum throughout the bounded Q range

The actual high family now has a uniform countable dyadic maximum for every real Q >= 2, including the entire bounded-Q range. A fixed effective-cutoff lower bound follows from the unconditional conductor-majorant ratio bound. The general power-decay maximum supplies ordinary and exceptional majorants; the exceptional bound retains a summable conductor power. Raw Page uniqueness controls the actual finite set of occurring data, and the finite-to-countable argument gives the full source family. The source-radius and real starting-threshold restriction are included, and the output function equals the actual pointwise supremum. No PNT input is needed for this uniform bound. The final source review must also verify that the convenient broad-masked circle model agrees with the manuscript's complementary narrow cutoff in its allowed geometric range.

`Checkpoint_776_Proposition621.md`

Checkpoint 776: Complete both high estimates including the full bounded Q range

Both maximal and individual-output estimates now hold for the broad-masked high model for every Q >= 2 and every real starting threshold N0 >= 2. The theorem combines the sharp large-Q estimate with the independently verified uniform bounded-Q maximum. Its precise epsilon formulation has the leading coefficient 2+epsilon and uses max(2,log Q) only in the harmless bounded-Q convention; it is exactly sqrt(log Q)/log log Q once log Q >= 2. The output is the actual pointwise countable supremum in real lp2. The last source-identification stage verifies that this convenient model equals the manuscript's unmasked complementary cutoff throughout the allowed source range before awarding the paper claim.

Checkpoint_777_SourceHighUniformGeometry.md

Checkpoint 777: Verify the original source range uniformly supplies the exact cutoff geometry

The manuscript's actual allowed range now implies the cutoff-containment geometry uniformly from every real N0 >= 2. One fixed positive c0 is chosen independently of epsilon. If Q >= 2 and log Q <= c0 sqrt(log N0), the constraint itself forces N0 past the existing uniform source threshold; hence every integer scale N >= N0 satisfies 2 R(N,Q)^8 <= N^2. This proof uses the established uniform fourth-power source budget and checks the exact parsing of its constant. The stronger squared working radius allows both ordinary and exceptional narrow cutoffs to be compared with the broad cutoff, without incorrectly assuming that the exceptional effective threshold is at most R.

Checkpoint_778_Proposition621Source.md

Checkpoint 778: Complete the exact source Proposition 6.21, both maximal and individual clauses

Both clauses of the actual source Proposition 6.21 are complete checked implications. The final declaration chooses one positive c0 before epsilon, retains the full real Q >= 2 and N0 >= 2 allowed range, constructs the actual countable lp2 supremum and the individual-output bound, handles changing genuine exceptional data, preserves the sharp leading coefficient 2, and includes a separately proved bounded-Q range. The exact source identification is part of the conclusion: the circle multiplier equals the periodization of the manuscript's unmasked complementary narrow-cutoff formula at every valid scale. The uniform source-range geometry and the coverage of every dyadic scale are proved. PNT limits, the general smooth multifrequency/sampling input, raw Page uniqueness and source-compatible exceptional-data existence remain explicit independent boundaries; no own-paper maximal estimate is assumed. The source-level registry awards only Proposition 6.21, changing it from partial to complete conditional; Theorem 1.1 is preserved and the stronger auxiliary lemmas remain partial. The completion report, statement review and remaining-work plan are packaged. The manuscript and all accepted replacement hashes are unchanged.

`Checkpoint_779_IntegerReflection.md`

Checkpoint 779: Integer reflection is an involutive lp isometry and reverses support intervals

Spatial reflection is defined by Rf(x)=f(-x). The new IntegerReflection module proves membership in every lp space is preserved, reflection is involutive, and its norm is unchanged for every p>=1, including p=infinity. It constructs an actual linear isometric equivalence over any normed scalar field, so the real and complex sequence spaces used by the paper are both covered. It also proves that finite input functions and finite indicators reflect exactly, that finite-set cardinalities are preserved, and that the integer interval [a,b] becomes [-b,-a]. These are unconditional algebraic and sequence-space proofs; the independent square-average theorem is not assumed or formalized here. This checkpoint is the foundation for the convolution and square-sign transfer. The completed conditional Theorem 1.1 and Proposition 6.21 are retained. A stale generated progress paragraph was corrected to agree with the already-verified Proposition 6.21 completion. The manuscript and all accepted replacements are unchanged.

Verification

All 846 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4453-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2136 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 848 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results under their paper hypotheses remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. In addition, Lemma 3.21 and BOTH conclusions of Theorem 1.1 are complete checked implications under their explicit independent deep inputs. The PNT limits are used in the sharp Gauss/high bound; an imported PNT bridge is not integrated. Both source clauses of Proposition 6.21 are also complete checked implications under their recorded independent inputs. The whole paper, Proposition 4.19 and the later headline applications remain unfinished. See docs/THEOREM_1_1_EXTERNAL_INPUTS.md. PNT limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_780_ReflectedConvolution.md`

Checkpoint 780: Reflection preserves convolution pairings and all decomposition constants

For an arbitrary complex kernel K, reflection K^R(z)=K(-z) satisfies the exact finite convolution identity (K^R*f)(x)=(K*(Rf))(-x) when the finite input set is also reflected. The module proves the corresponding finite complex and indicator pairings, with both input and output sets reflected and their cardinalities preserved by checkpoint779. It constructs R T R for continuous linear operators between any lp and lq with p,q>=1, including infinity, and proves exact equality of their operator norms. The actual OperatorHighLowBound, OperatorOrliczBound and KernelL2Bound predicates are each equivalent for K and K^R with every numerical parameter and constant unchanged. The low/high/error maps need not be linear; their norm bounds transfer through the involutive isometry. No analytic input is used for these results. This closes the general convolution-estimate part of the requested sign transfer; the next checkpoint identifies the literal plus-square formulas and support windows.

PNT limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

Checkpoint_781_SquareAverageReflection.md

Checkpoint 781: Full and annular plus-square formulas equal reflected minus-square averages

The plus-square operators and kernels are defined directly by finite sums, independently of reflection. Lean proves that their convolution kernel is the reflection of the existing minus-square kernel and their operator is R T_- R. The full weighted average is exactly N^-1 times the sum over 0<n<=N of w(n)f(x+n^2); the annular version retains the exact natural-index range N/2<n<=N. Both are equivalent by involutive conjugation to the existing x-n^2 operators, with equal operator norms. The proofs allow arbitrary real arithmetic weights; neither n nor w(n) is negated. They therefore apply unchanged to ordinary square weights and von-Mangoldt weights. The positive-translation kernel is supported in [-N^2,-1], and its local input window is [x,x+N^2]. Lean proves the interval reflection and the actual indicator-convolution localization on that window. This is an exact transfer after reflecting the geometry, not a claim that an asymmetric support interval or a particular dyadic grid stays fixed. No manuscript replacement is required. The external analytic square theorem is untouched.

Checkpoint_782_MaximalReflection.md

Checkpoint 782: Reflection transfers actual maximal bounds and temporal majorants

Spatial reflection transfers arbitrary families of lp-to-lq maps, including the l-infinity endpoint. The new LpFamilyMaximalBound predicate requires bounded coordinate norm ranges, an actual real-valued lp representative of their supremum, and the stated norm bound. The proof reflects that representative and proves equivalence of the maximal estimate for T_i and R T_i R with the same constant. No summability of operator norms or additional analytic maximal theorem is assumed. The already-used FiniteTemporalMajorants predicate is likewise equivalent for a family and its spatial reflection. Norms of operator-output differences are also preserved, recording the algebraic ingredient for variation and difference estimates without claiming to formalize a separate variational theorem. All these results are unconditional transfer lemmas. The independent ordinary-square analytic theorem and its globalization remain external until separately proved; this checkpoint supplies no new analytic assumption.

PNT limits, raw compatible progression/Ren/Ghosh data, and the independent square decomposition remain explicit hypotheses. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_783_SquareDecompositionReflection.md`

Checkpoint 783: Complete the square-sign reflection and integrate it into Theorem 1.1

The requested square-sign reflection is complete. The new PositiveFullSquareDecompositionInput states the independent ordinary-square global high/low hypothesis using the literal x+n^2 kernel. Lean proves it equivalent to the existing FullSquareDecompositionInput at exactly the same constant C, then derives the existing minus-sign and plus-sign annular inputs with the already proved factor 3C. The final theorem_1_1_from_positive_square_input accepts the positive-sign global hypothesis and returns both existing conclusions of Theorem 1.1 for the paper's actual minus-sign prime-square average, without adding an analytic assumption. The literal von-Mangoldt sum and the reflected source interval [-2N^2,N^2] are checked. Together with checkpoints779-782 this proves the lp isometries through infinity, general convolution and pairing identities, high/low/error constant transfer, full/annular formulas, actual maximal-bound transfer and support/localization changes. Reflection is removed from the unformalized boundary; the independent ordinary-square analytic theorem and its local-to-global passage remain explicit global hypotheses. The manuscript is unchanged. Current external-input, statement-review, completion and work-plan documents are reconciled; paper claim statuses remain 10 proved,3 conditional,6 partial,1 external candidate,34 open. The blueprint-length report distinguishes topic/reference notes, individual checkpoint expositions and overlapping batch summaries; the old 19-page PDF is only the initial blueprint, and there is no current combined PDF. See docs/SQUARE_REFLECTION_COMPLETION.md and docs/BLUEPRINT_LENGTH.md.

Reflection between plus and minus square translations is proved without any extra analytic assumption. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_784_PageDistributionInputs.md`

Checkpoint 784: Compatible Page zero and raw distribution data for one common operator family

The refined PagePrimeSquareDistributionInputs interface supplies compatible optional genuine Page-zero data together with the existing raw progression-prefix and Ren/Ghosh estimates. Its existence remains an explicit independent number-theoretic hypothesis, not a new Lean axiom and not an own-paper operator conclusion. The module proves that this refined input supplies the already used PrimeSquareDistributionInputs, so it preserves the fixed-scale Theorem 1.1 route. It defines one chosen exceptional datum for each N,Q and proves its raw analytic and Page-region properties whenever the original range is admissible. The choice is independent of the high-bound epsilon and every error-decay exponent; this is needed to assemble all estimates for the same three operators. The optional trivial-character case and positive conductors are checked. The full Proposition 4.19 still requires the fixed operator-family construction, all-input local low bound, uniform all-scale error estimates and final quantifier review. Theorem 1.1, Proposition 6.21 and the completed reflection bridge are preserved, and the manuscript is unchanged.

Checkpoint_785_SelectedPrimeSquareOperators.md

Checkpoint 785: Exact common low high and error operators on all inputs

Defines the actual low, high and error operators using one fixed optional Page datum and the manuscript radius sourceMajorArcScale N Q. None of these definitions depends on epsilon or an error exponent. Lean proves the exact continuous-linear-operator decomposition on all l2 inputs, not just indicators, using the exact annular Fourier identity. It also proves the identity on all l1 inputs with the low term realized as the genuine l1-to-l-infinity operator and the high/error inputs included into l2. The selected high tail is exactly the already verified dyadic source tail from Proposition 6.21, with the original starting-threshold mask and all dyadic scales at least two. This checkpoint establishes common operator identity and compatibility, without yet awarding any of the missing uniform bounds or closing Proposition 4.19. All existing completed results and the manuscript are preserved.

Reflection between plus and minus square translations is proved without any extra analytic assumption. The smooth multifrequency boundary is only for later maximal applications.

Checkpoint_786_SourceLocalMass.md

Checkpoint 786: Literal real-radius local maximal average and extension to all l1 inputs

Defines the literal local average in Proposition 4.19 for every l1 input: the supremum over all real M>=N of M^-2 times the sum of |f(y)| over |x-y|<=M^2. Lean proves summability, positivity, boundedness of the supremum, and its l1 norm majorant. It proves that each finite dyadic local mass already used by the low-kernel analysis is dominated by this all-input source supremum, taking M=sqrt(2^j N^2). A general continuous convolution lemma then extends any existing finite-input dyadic local bound to the actual l1-to-l-infinity Fourier operator on all l1 inputs, using a proved convergent sum rather than a density assertion left informal. Thus the final local clause will use the printed source quantity with the absolute

radius constant C=1. This is an unconditional supporting proof and adds no analytic input. The selected family, independent-input boundaries, completed prior results and manuscript remain unchanged.

`Checkpoint_787_SelectedPrimeLowBounds.md`

Checkpoint 787: Both low clauses on every l1 input with an absolute source range

Both actual low-term clauses of Proposition 4.19 are now proved for the common selected operator family, on every l1 input. One positive absolute source-cutoff coefficient is chosen before all data, epsilons and error exponents. The exact l1-to-l-infinity norm is bounded by (2 lowSpatialConstant) N^-2 Q log(2Q), and the pointwise local bound by (8 lowSpatialConstant) Q log(2Q) times the literal all-real-radius sourceLocalMass. The latter is the printed source supremum with C=1. A proved general cutoff-forcing lemma shows that a sufficiently small fixed coefficient in log Q<=delta sqrt(log N), together with Q>=2, forces any fixed starting threshold. This handles the low-term threshold without weakening the source N-range. No own-paper low estimate or local-to-global assertion is assumed. The existing raw number-theoretic boundary remains explicit, and no manuscript replacement is needed.

`Checkpoint_788_FinitePageErrorBound.md`

Checkpoint 788: Uniform finite-scale error envelope for every real cutoff and Page datum

Proves an elementary error-operator envelope uniform over every real Q>=2 and every optional Page datum on each finite range 2<=N<=T, whenever the source cutoff geometry holds. The geometry implies sourceMajorArcScale N Q<=N, so all rational centers lie in one finite canonical set. The annular average is bounded by a finite sum of its actual operator norms, and the major-arc model by the already proved Gauss coefficient envelope. Their exact difference bounds the actual error. No asymptotic error estimate, distribution estimate or new analytic hypothesis is used. This finite-range result will close the small-scale part of every A-dependent error-decay estimate while preserving one A-independent source coefficient and one fixed selected operator family. It does not award the full Proposition 4.19 yet. The existing manuscript and completed results remain unchanged.

explicit hypotheses. Reflection between plus and minus square translations is proved without any extra analytic assumption. The smooth multifrequency boundary is only for later maximal applications.

Checkpoint_789_SelectedPrimeErrorBounds.md

Checkpoint 789: Every error exponent with one fixed source range and operator family

The actual selected error operator now satisfies Q^(-1/2)(1+log N)^(-A) decay for every real A>=0, with one positive source-cutoff coefficient chosen before A. The same operator uses the same N,Q-dependent Page datum for every exponent. Large N uses the existing proved all-point circle approximation from raw progression/Ren/Ghosh data; the finitely many smaller arithmetic scales use the unconditional envelope from checkpoint788. Geometry bounds Q by the finite threshold, allowing the constant depending on A to absorb those scales. Thus no A-dependent narrowing of the final source range or A-dependent replacement of the error operator is used. The resulting bound has logarithmic Q power zero, which implies the source's allowed polynomial-logarithmic loss. Raw data existence remains the explicit refined independent input, not an assumed error estimate. This completes the error component needed by Proposition 4.19 without awarding the separate stronger source approximation lemma, whose full statement has not been reviewed here.

Checkpoint_790_SelectedPrimeHighBounds.md

Checkpoint 790: Sharp fixed and countable maximal high bounds for the common selected family

The common selected high family now has both clauses required by Proposition 4.19: the exact fixed dyadic-scale l2 operator norm and the actual countable l2 supremum from every real starting threshold, for every real Q>=2. A single positive cutoff coefficient is selected before epsilon; one positive K for each epsilon works uniformly over Q, all scales and starting thresholds, and all inputs. Bounded Q and the sharp leading 2+epsilon coefficient are inherited from the fully checked Proposition 6.21. The proof constructs compatible genuine Page data at every valid scale from the refined raw distribution selector, using a proved range-forcing lemma. It retains the exact source periodized high-symbol identity and changing exceptional characters. No own-paper maximal theorem is an external assumption. The

only independent inputs used for this component are the two prime limits, the general smooth multifrequency/sampling input, raw Page uniqueness and compatible raw progression/Ren/Ghosh data existence. The fixed estimate is deduced from the very same maximal family. The final Proposition 4.19 export and source review remain to be packaged.

<!-- checkpoint-verification -->

Verification

All 857 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4464-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2212 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 859 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results under their paper hypotheses remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. In addition, Lemma 3.21 and BOTH conclusions of Theorem 1.1 are complete checked implications under their explicit independent deep inputs. The PNT limits are used in the sharp Gauss/high bound; an imported PNT bridge is not integrated. Both source clauses of Proposition 6.21 are also complete checked implications under their recorded independent inputs. The whole paper, Proposition 4.19 and the later headline applications remain unfinished. See docs/THEOREM_1_1_EXTERNAL_INPUTS.md. PNT limits, raw compatible progression/Ren/Ghosh data, and the global independent square decomposition remain explicit hypotheses. Reflection between plus and minus square translations is proved without any extra analytic assumption. The smooth multifrequency boundary is only for later maximal applications.

`Checkpoint_791_Proposition419.md`

Checkpoint 791: Complete every source clause of Proposition 4.19 with one common operator family

Completes every displayed clause of the actual source Proposition 4.19 as one checked implication. The final proposition419 export proves Proposition419Bounds for the same selected low, high and error family, with one positive cutoff coefficient chosen before epsilon and every error exponent. It includes the exact all-input decomposition, the genuine low l1-to-l-infinity norm, the literal real-radius local low bound for every l1 input, both sharp fixed and countable maximal high estimates for every real Q>=2 and every allowed starting threshold, every A>0 error rate without an extra Q logarithm, and the exact printed high-symbol identity. The dyadic coverage theorem excludes the impossible N=1 case and covers every admissible original dyadic scale. Genuine Page-data selection from the refined raw interface is integrated; raw data existence, the two prime limits, raw Page uniqueness and the general smooth multifrequency/sampling theorem remain explicit independent hypotheses. No own-paper operator conclusion is assumed and no manuscript correction is needed. The exact source review awards only Proposition 4.19, moving it from partial to complete conditional; the whole paper and stronger auxiliary statements remain unfinished. Theorem 1.1, Proposition 6.21 and reflection are preserved. The updated inventory has 54 claims:10 proved,4 conditional,5 partial,1 external candidate,34 open, with 4 definitions separate. The next source-level milestone is sparse domination and Theorem 1.3.

Verification

All 858 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4465-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2214 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 860 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results under their paper hypotheses remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. Lemma 3.21, both conclusions of Theorem 1.1, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. The whole paper, the stronger printed auxiliary lemmas and the later sparse/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved.

Checkpoint notes 792-866

Checkpoint_792_SparseIntegerIntervals.md

Checkpoint 792: Define genuine integer sparse families and the two source forms

Defines nonempty integer intervals, their exact cardinalities, fivefold dilation and support-ball containment. Defines the actual finite-set endpoint and power sparse forms with the printed densities and records sparsity through actual pairwise disjoint major subsets. The parameter is explicit: the preliminary definition uses 1/4 and Theorem 1.3 uses 1/10. Proves elementary positivity and monotonicity of sparsity. These are foundations only; no source sparse theorem is awarded from definitions. The previously completed conditional results remain unchanged.

Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved.

Checkpoint_793_FiniteSparseMajorSets.md

Checkpoint 793: Construct actual disjoint major subsets and retain them under dilation

Proves that deleting the union of strict descendants in a finite laminar interval family gives actual pairwise disjoint major subsets, with the cardinality prescribed by the packing inequality. Proves fivefold dilation preserves those very subsets while dividing the sparsity constant exactly by five. Thus a 3/4-sparse parent family produces a genuine 1/10-sparse family of fivefold intervals, with no unproved grid replacement. The construction of the stopping intervals and the analytic local estimates remain separate unfinished deductions.

Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved.

`Checkpoint_795_IntegerIntervalWeakCounting.md`

Checkpoint 795: Prove the finite weak density bound and quantitative stopping packing

Proves the counting-measure weak (1,1) inequality for the union of all intervals in a finite family whose F-density exceeds a given threshold. The constant is 3 and follows from the checked disjoint interval selection and exact finite intersection counts. Derives a concrete stopping packing bound: at threshold 64|F|/L the bad union has cardinality at most L/4. This supplies the quantitative packing ingredient without assuming a maximal-function theorem.

`Checkpoint_796_FiniteSparseGluing.md`

Checkpoint 796: Prove exact gluing of recursive interval costs and packing

Proves finite gluing below pairwise disjoint stopping children. The interval subfamilies are disjoint as finite sets, the strict-descendant union at every interior node stays in its original child construction, the

parent packing bound propagates, and the recursive cost sum is exactly the sum over the glued finite family. No sparse recursion is assumed in these algebraic and cardinality deductions.

These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved.

`Checkpoint_797_FiniteSparseRecursion.md`

Checkpoint 797: Prove termination and sparse cost summation of the finite stopping recursion

Proves termination and cost summation of finite interval stopping recursion by strong induction on integer length. A one-generation recursive inequality and quarter-packing produce a finite family with actual 3/4-sized pairwise disjoint major subsets and the required summed cost. The local one-generation inequality is explicitly a hypothesis of this abstract theorem and still has to be proved for the actual averages; it is not declared an external analytic input or the completed paper recursion.

`Checkpoint_798_StoppingPairingMajorants.md`

Checkpoint 798: Prove actual varying-scale high and low pairing bounds from Proposition 4.19

Proves finite variable-scale pairings from genuine real l2 pointwise majorants, then applies the exact countable high maximum and local low estimate of completed Proposition 4.19 at an arbitrary spatially varying dyadic arithmetic scale. The high pairing uses the actual supremum representative and its l2 norm. A fixed-scale norm is not substituted. These estimates are deductions from Proposition 4.19; no new external input is used. The local error maximum, ordinary-square stopping boundary and final sparse assembly are still separate work.

Checkpoint_803_IntegerBadComponentNeighbors.md

Checkpoint 803: Find genuine good neighboring points and prove strict stopping-length decrease

Proves that each maximal consecutive bad interval has good neighboring points whenever those neighbors lie in the parent. A quarter-packing bad set leaves a good point, each component is strictly shorter than the parent, and every point in a component has a good parent point at distance at most the component length. These facts supply both termination and the admissibility of the remaining stopping scales.

Verification

All 870 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4477-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2279 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 872 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results under their paper hypotheses remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. Lemma 3.21, both conclusions of Theorem 1.1, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. The whole paper, the stronger printed auxiliary lemmas and the later sparse/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved.

Checkpoint_804_GoodPointLocalMass.md

Checkpoint 804: Control the full real-radius local average from a nearby good point

Proves that a good nearby point controls sourceLocalMass at every real radius M>=N, not merely at dyadic radii. Establishes exact finite-indicator ball counts, integer centered-ball geometry and the bound sourceLocalMass <= 5t from tested interval densities and the parent density. This supplies the analytic/geometric bridge required by the actual low operator of Proposition 4.19.

This checkpoint passes a 4478-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2284 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 873 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results under their paper hypotheses remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. Lemma 3.21, both conclusions of Theorem 1.1, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. The whole paper, the stronger printed auxiliary lemmas and

the later sparse/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved.

`Checkpoint_805_PrimeStoppingGeometry.md`

Checkpoint 805: Construct quarter-packed stopping children and prove actual source admissibility

Constructs the actual parent bad set by testing every integer subinterval of the fivefold parent at density threshold 64|F|/|I|. Proves quarter packing, exact covering by disjoint maximal bad components, strict decrease of their lengths and the good-point density property. For every remaining arithmetic scale N, proves the literal sourceLocalMass bound <=320|F|/|I|, uniformly over every real radius M>=N. These deductions supply admissibility rather than assuming it.

`Checkpoint_808_PrimeRemainingScaleRecursion.md`

Checkpoint 808: Prove the exact one-generation recursion for the actual prime-square maximum

Proves the actual one-generation finite maximal recursion. Every dyadic arithmetic scale is assigned either to the admissible remaining-scale maximum or to the unique smaller stopped interval containing the point. The residual average is identified exactly with the child-localized original kernel using proved compact support, and the finite test pairing is bounded by the parent remaining contribution plus the exact sum of child maximal pairings. No final local endpoint estimate is assumed in this decomposition.

Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved.

`Checkpoint_809_IndependentStoppingInputs.md`

Checkpoint 809: Record the precise independent stopping and maximal analytic boundaries

Records two explicit independent analytic interfaces needed for sparse applications: the ordinary-square stopping low/high decomposition, and complementary-exponent prime-square maximal Lp pairings. Their existence is not proved or added as a Lean axiom. The ordinary input is stronger than the earlier fixed-scale square interface. The support, normalization, admissibility and sign adaptations remain within its unformalized scope, as do prime normalization and prime-power extension in the maximal input. Proves monotonicity of the square constant and restriction of the maximal test set. No endpoint improving or sparse conclusion of this paper is a field of these predicates.

Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_810_AdmissibleAnnularLinearization.md`

Checkpoint 810: Prove exact admissible linearization and the sparse deduction from a local estimate

Proves exact finite linearization of the remaining-scale maximum on its actual active test set. The chosen dyadic scale attains that maximum, satisfies the parent spatial cutoff and the proved local-average admissibility bound. Combines the actual one-generation recursion with the terminating laminar construction to obtain a genuine finite 3/4-sparse bound from an explicit admissible local estimate. That local estimate remains a deduction to be supplied from the recorded analytic inputs, not a newly assumed independent result.

`Checkpoint_816_PrimeLargeStoppingPairing.md`

Checkpoint 816: Prove the actual uniform large-stopping-scale prime pairing

Proves the actual uniform large-stopping-scale prime pairing from the common family in Proposition 4.19. All constants are chosen before the interval, input and reference sets, varying arithmetic scale, dyadic Q and starting threshold. The low local bound, actual countable high maximum and actual valid-error maximum are combined with the same selected Page data and normalized to the checked scalar expression. No own-paper pairing conclusion is an external input.

Verification

All 883 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4490-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2326 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 885 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed numbered results under their paper hypotheses remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, Theorem 4.1 and Corollary 4.15. Lemma 3.21, both conclusions of Theorem 1.1, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. The whole paper, the stronger printed auxiliary lemmas and the later sparse/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved. Sparse applications additionally record OrdinarySquareStoppingInput CS and IndependentPrimeMaximalInput as explicit independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_817_PrimeStoppingThreshold.md`

Checkpoint 817: Construct the balanced source-range starting threshold

Constructs an explicit starting scale from Q and the positive source cutoff coefficient. Proves it is at least 2, satisfies the exact Proposition 4.19 range, and has logarithm at most a fixed multiple of paper-Log(delta)^2 whenever the balanced log Q bound holds. The coefficient is uniform in the interval, sets and density.

Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_819_PrimeStoppingLocalEndpoint.md`

Checkpoint 819: Prove the actual sharp admissible prime-square local endpoint

Proves the actual admissible prime-square local endpoint, uniformly in every parent interval, finite input/reference/test sets and varying dyadic arithmetic scale. The density retains the larger reference test set. Small scales use the proved prime-to-ordinary comparison and the independent ordinary low/high

input; large scales use the exact common Proposition 4.19 family and the proved scalar balance. The sharp coefficient is every cstar>4sqrt(3)/9, all bounded densities are included, and fixed logarithmic powers are absorbed by the actual paper Phi. No local endpoint conclusion is an assumed input.

`Checkpoint_827_SparseDyadicQualification.md`

Checkpoint 827: Check and document the required dyadic scope of the abstract recursion

Proves a concrete positive compactly supported convolution counterexample showing why the abstract recursion lemma must specify a dyadic maximum when its local hypothesis tests only dyadic stopping values. The kernel is zero at every dyadic index and equals the identity at N=3; all local dyadic pairings vanish but the unrestricted maximum is at least one on singleton test sets. Saves a proposed statement qualification for source Lemma 5.10 (l:sparserecursion) and a precise all-cutoff reduction paragraph for Theorem 1.3. These are proposed only, not applied to the current manuscript. The actual prime-square all-cutoff comparison and both sparse conclusions are already proved separately, so no new hypothesis is added to them.

Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_828_TheoremOneThree.md`

Checkpoint 828: Complete both source conclusions of Theorem 1.3 with actual sparse families

Both source sparse conclusions are complete. The final theorem_1_3 proves the sharp endpoint for every cstar>4sqrt(3)/9 and the full open triangle, with actual finite interval families and pairwise disjoint major subsets of size at least one tenth. The literal full maximal indicator covers every integer N>=2. All local endpoint, stopping, support, packing, recursion, interpolation and all-cutoff deductions are proved. Independent raw distribution/Page, prime-limit, smooth multifrequency/sampling, ordinary-square stopping and complementary-exponent maximal inputs remain explicit hypotheses, not new Lean axioms. A checked counterexample motivates an unapplied dyadic scope clarification for abstract Lemma5.10; the actual prime-square theorem already has the required all-cutoff comparison. Only Theorem1.3 gains full source completion credit; three general Section5 auxiliary statements gain partial credit, and the rest of the paper remains unfinished.

This checkpoint passes a 4502-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2367 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 897 Lean files pass

the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved. Sparse applications additionally record OrdinarySquareStoppingInput CS and IndependentPrimeMaximalInput as explicit independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_829_NearOneGauge.md`

Checkpoint 829: Literal Section7 Orlicz gauge and convexity

The literal Section7 integrand and its primitive Psi_C are defined. A continuous clamp extends the density to negative arguments and is proved identical to the printed formula for every nonnegative argument. Lean proves positivity, monotonicity and continuity of the density; the fundamental theorem of calculus for Psi_C; its continuity, monotonicity and convexity; Psi_C(0)=0; Psi_C(t)>=t for C>=0,t>=0; and the upper comparison Psi_C(t)<=t exp(C rate(t)). No analytic theorem is assumed. The matching lower comparison, doubling, quantitative optimization and all operator conclusions remain to be developed. This checkpoint does not close Theorem t:orlicz-maximal (archived number7.2) or either ergodic corollary.

`Checkpoint_830_NearOneGaugeComparison.md`

Checkpoint 830: Orlicz gauge comparison and doubling with explicit constants

The matching lower comparison and doubling of the literal Section7 gauge are now proved. A direct algebraic logarithmic tangent estimate proves sqrt(y log(e+y)) <= sqrt(x log(e+x))+2(y-x) for 1<=x<=y. Consequently the actual density satisfies the fixed-rescaling bound exp(2 C log a) for every a>=1. Integration over the final half interval gives the lower gauge comparison, and together with the upper comparison proves the displayed asymptotic equivalence in e:orlicz-gauge-comparison with explicit constants and a doubling inequality. These are unconditional scalar and integration deductions. No IW, maximal, modular or ergodic bound is assumed or claimed here.

independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_831_NearOneQuantitativeGrowth.md`

Checkpoint 831: Quantitative Orlicz power absorption uniform near one

Lean proves the quantitative small-power absorption required near p=1. For every C>=1, 0<e<=1 and v>=1, C sqrt(v log(euler+v)) <= e v/2 + K(C)/e log(euler/e), where K(C)>0 is explicit and independent of e,v. Here euler means exp(1), while the variable e is p-1. The proof uses a logarithmic tangent inequality and a squared Young inequality, with no asymptotic implicit constants. Substituting the literal gauge logarithm gives density_C(t) <= exp(K(C)/e log(exp(1)/e)) (exp(1)+max(0,t))^(e/2) for every real t. This is the scalar dependence in c:orlicz-p; the operator distributional estimate and layer-cake integration are not assumed or claimed proved at this checkpoint.

`Checkpoint_832_FiniteDistributionBounds.md`

Checkpoint 832: Finite testing and actual distributional cardinal bounds

A finite-test distribution formalism is proved equivalent to finiteness and the actual level-set cardinal bound. Infinite level sets cannot silently receive cardinality zero: arbitrarily large finite subsets give a checked contradiction. Lean proves Chebyshev bounds for every positive real exponent, their actual lp-space specialization, monotonicity, the two-term distribution union estimate, and the finite-family sum estimate. These are the counting tools for Section7 high-low and layer-cake deductions. They contain no arithmetic, restricted endpoint or modular estimate as an assumed external theorem.

`Checkpoint_833_NearOneLayerAbsorption.md`

Checkpoint 833: Global absorption of dyadic layer losses by the literal gauge

The dyadic layer-cake loss is absorbed into the literal gauge by proved uniform rescaling estimates. Lean proves coefficient monotonicity, rate(t)>=sqrt(log(exp(1)+t)), log(v)<=2sqrt(v) for v>=1, and a general variable-rescaling inequality when log(a)<=L+d rate(t). In particular a factor bounded by D log(exp(1)+t)^2 changes C to 9C+4 with an explicit constant depending only on C,D. This replaces the informal little-o sentence in the source by a global bound, including all bounded layers. The maximal operator restricted estimate is not assumed here, and its arithmetic derivation remains to be connected.

`Checkpoint_834_PositiveAverageMaximum.md`

Checkpoint 834: Genuine positive averaging maxima and finite layer majorization

The genuine countable maximum of a general positive finite averaging family is constructed and controlled. The family records its actual integer shifts, finite index sets, nonnegative real weights and a uniform mass bound. For bounded inputs the supremum range is proved bounded, every original average is dominated, and the maximum is nonnegative. The complex finite averages satisfy the exact indicator identity and a finite layer-majorization theorem with the correct mass contribution of the bounded remainder. These are proved algebraic and order facts, ready for the actual square, von Mangoldt and prime normalizations. No endpoint or IW estimate is a field of the family.

`Checkpoint_835_DyadicFunctionLayers.md`

Checkpoint 835: Actual finite dyadic layers and exact cost partition

The finite dyadic layer decomposition is constructed for arbitrary complex finitely supported inputs. A chosen integer height satisfies the exact dyadic bracketing; layers are actual finite subsets, pairwise disjoint, and their indices form a finite set. Lean proves exact partition of layer costs and pointwise domination of the input by the bounded remainder plus the weighted indicators. The half-open convention at dyadic boundary values is explicit, and does not discard points. This step is algebraic and does not assume a restricted weak estimate.

independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_836_DyadicLayerGaugeCost.md`

Checkpoint 836: Uniform dyadic gauge costs and truncated level-set sum

The literal gauge pays for all dyadic layer costs globally. For K>=2 and every natural layer j, Lean proves Psi_C(4*2^j*(j+1)^2) <= L(C,K) Psi_(9C+4)(2^j/K) with an explicit positive constant. The proof includes the bounded layers and all dyadic endpoints. A checked finite inverse-square sum bound controls the threshold allocation, and exact layer partitioning gives the truncated modular cost summed over the actual set where |f|>lambda/K. No asymptotic sentence or unproved rearrangement of infinite sums is used.

`Checkpoint_837_RestrictedToModular.md`

Checkpoint 837: Complete finite layer-cake passage from restricted to truncated modular estimates

The general restricted-to-truncated-modular implication is proved for a genuine countable positive averaging maximum. Starting with a restricted indicator distribution bound (a reusable internal hypothesis, not an independent prime-square input), Lean constructs the finite layers, proves the threshold union inclusion, pays the threshold sum, applies the restricted estimate to every actual layer, and absorbs its cost by the literal Psi_(9C+4). The result has C0=2 times the actual mass bound and the exact input truncation |f|>lambda/C0. No circular claim that the actual arithmetic restricted estimate is already proved is made. The actual restricted estimate must still be obtained from the IW/arithmetic argument before source Theorem t:orlicz-maximal (archived number7.2) can be declared complete.

`Checkpoint_838_ActualPositiveSquareFamilies.md`

Checkpoint 838: Actual square von Mangoldt and prime averaging families

All three averaging families in the printed Section7 theorem now instantiate the positive finite-family framework. They use the literal square shifts x-n^2. The von Mangoldt family uses Mathlib Lambda including prime powers and the proved Chebyshev mass bound. The ordinary-square family uses 1/N. The unweighted-prime family uses the actual primesLE finite set and Mathlib primeCounting pi(N), with exactly the normalization 1/pi(N). Their actual finite averages and countable maxima over every integer N>=2 are proved identical to the concrete formulas. The common uniform mass bound is proved without PNT. No modular, near-L1 or IW estimate is inferred from mass alone.

`Checkpoint_839_NearOneGaugeMoment.md`

Checkpoint 839: Actual improper Orlicz moment and quantitative power integral

The actual improper gauge moment in c:orlicz-p is now controlled. Lean proves a global power majorant for Psi_C(u) on every interval u>=a>0, with an explicit constant containing exp(K(C)/(p-1) log(exp(1)/(p-1))). It proves actual integrability of Psi_C(u) u^(-p-1) over (a,infinity), and bounds its integral by an explicitly integrated power. This uses the checked literal gauge, continuity and Bochner improper integrals, and never replaces a divergent totalized integral by a number. The operator layer-cake and actual restricted arithmetic estimate remain separate obligations; this scalar result alone does not close c:orlicz-p.

Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved. Sparse applications additionally record OrdinarySquareStoppingInput CS and IndependentPrimeMaximalInput as explicit independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_840_QuantitativeIWParameters.md`

Checkpoint 840: Literal quantitative Ionescu-Wainger parameters and separation

The quantitative Ionescu-Wainger scalar parameters from e:IWparameters7 and e:orlicz-D are defined with their printed powers and logarithms. Lean proves 1<p_r<=4/3, the exact identities p_r-1=1/(2r-1) and 1/p_r=1-1/(2r), and the rho range, half-exponent and exact floor-rank relation for k>=4. It proves B>=1, its exact logarithm, epsilon>0 and the strict separation inequality 4 epsilon B^2<1. All are unconditional algebraic deductions; existence of the IW sets, multiplier and sampling estimates has not been supplied by an assumption or declared proved. Natural Q is enough for the later dyadic parameter choice; the full printed real-Q proposition is not awarded.

Verification

All 907 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4514-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2456 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 909 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved. Sparse applications additionally record OrdinarySquareStoppingInput CS and IndependentPrimeMaximalInput as explicit independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations

remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

Checkpoint_841_NearOneMomentExponential.md

Checkpoint 841: Exact exponential dependence on p minus one in the gauge moment

The scalar moment has the exact near-L1 exponential dependence displayed in c:orlicz-p. For C,C0>=1 and every 1<p<=2, Lean proves actual integrability on (1/C0,infinity) and bounds the integral of Psi_C(u)u^(-p-1) by exp(K(C,C0)/(p-1) log(exp(1)/(p-1))). The constant is explicit and quantified before p. The proof includes the lower cutoff, reciprocal power, prefactor absorption, and all p in the stated range. This is an unconditional scalar theorem. It does not assume or declare proved the operator modular estimate, its layer-cake norm implication, or the final ergodic assertion.

Checkpoint_842_InitialPositiveDistribution.md

Checkpoint 842: Actual initial-scale mass and Chebyshev contribution

The initial-scale contribution to the Section7 restricted estimate is proved for actual positive finite averages. Translation injectivity bounds the finite sum of a shifted indicator by its cardinality. The actual complex average therefore has l1 mass at most mass*|F|. The sum over the first J averages has l1 mass at most J*mass*|F|, giving exactly t J mass |F| in the distributional estimate. Generic real power budgets, their actual lp-space specialization, and Chebyshev are also proved. No deep theorem or source high-low existence statement is a hypothesis of these initial-scale results.

`Checkpoint_843_HighLowRestrictedDistribution.md`

Checkpoint 843: Exact high-low restricted distribution deduction

The distributional high-low deduction underlying e:orlicz-optimize is proved for the genuine all-index maximum. Given actual large-scale low and high envelopes with finite p and 2 power budgets, the level set is controlled by t J mass |F|+(2t)^p B_low+4t^2 B_high. The proof finds a violating original scale from the supremum, separates the first J averages, performs the exact threshold union, and applies the proved Chebyshev bounds. It also proves the actual level set finite. The large-scale envelope premises are internal hypotheses of this reusable deduction, not authorized replacements for the paper own high-low existence theorem. Their construction remains open for Section7.

`Checkpoint_844_QuantitativeIWBalance.md`

Checkpoint 844: Uniform integer optimization for the Ionescu-Wainger loss

The integer optimization behind the quasi-polynomial Orlicz loss is proved uniformly. For every v>=1, choose k=ceil(sqrt(v/log(exp(1)+v)))+4. Lean proves k>=4, its two-sided rounding bounds, and k log(exp(1)+v)+v/k <=12 sqrt(v log(exp(1)+v)); a weighted version has the same bound multiplied by any fixed A>=1. This admissible alternative to the source eventual floor choice handles every bounded v directly. It proves the scalar balancing step, without assuming existence of any IW model or claiming that the full r,k,Q,N0,D parameter comparison has been discharged.
