      "scope": "Complete printed Theorem 7.2 as an implication of explicit independent standard inputs:
all three actual families (von Mangoldt squares, ordinary squares, unweighted prime squares), every
integer cutoff N >= 2, every complex finitely supported function and positive level, with common
absolute C, C0 and K >= 1. All three conclusions are proved, including finite level sets: the truncated
modular bound, unrestricted modular bound and restricted bound for every finite F and t >= 1. The final
theorem is stated with literal sums over all integers and finite support, using the actual integral
gauge. The ordinary branch derives the actual discrete circle-model error, maximal comparison, low/high
restricted bound and full-cutoff reconstruction from the independent scalar Weyl input and general IW
inputs; no own restricted or high/low conclusion is assumed. The unweighted-prime transfer uses proved
Mathlib Chebyshev bounds without a new PNT input. At checkpoint1264 the current public export consumes
the proved finite signed maximal theorem at constant6; a supplied RawFiniteSignedMaximalInput and its
constant R are no longer hypotheses.",
```

```
      "remaining": "No remaining clause of Theorem7.2 or Corollaries7.6/7.46 within the agreed
conditional scope. The explicitly recorded independent inputs and their published-theorem bridges remain
 unformalized. Stronger standalone auxiliary parameter/full-generality ranges and later badness/sieve
results remain separately tracked.",

      "scope": "Complete printed Corollary 7.6 as an implication of the already recorded Theorem 7.2
independent inputs. One absolute D > 0 works for all three actual families, every 1 < p <= 2 and every
integer lp input. The literal all-integer-cutoff maximal function is proved to belong to lp with norm at
 most exp(D/(p-1)*log(exp(1)/(p-1))) times the input norm. The actual truncated modular estimate,
general layer cake, singular power integral, quantitative constant absorption, p-th-root conversion and
all-input finite/Fatou extension are proved. At checkpoint1264 the current public export consumes the
proved finite signed maximal theorem at constant6; a supplied RawFiniteSignedMaximalInput and its
constant R are no longer hypotheses.",
      "remaining": "No remaining source clause within the agreed conditional scope; no new strong
maximal or layer-cake input is introduced. Theorem7.2's independent hypotheses remain explicit. The
ergodic Corollary7.46 and Theorem1.5(ii) are now separately completed under their reviewed independent
inputs.",

      "scope": "All four source clauses are complete conditional implications for one common
construction at every real Q>=2^k, r>=2 and k>=4. The literal B, epsilon and C_rk are retained; P<=3^Q,
every a/q modulo one with q<=Q, all denominator bounds and full goodness are proved. The rough
multiplier conclusion is an actual bounded operator on the entire integer lp space, with the exact
finite-convolution Fourier kernel, uniqueness and norm <=C_rk times the actual full real Lp operator
norm. The general full-Lp real/cyclic product bound and rank-one coefficient factorization are proved.
Both major-arc sampling directions, actual unique interpolation on the full distributional integer lp
Fourier-support class, the inverse-C_rk source inequality, and all finite-dimensional normed complex
Shannon targets throughout 1<=p<=infinity are retained. Point sampling uses the standard continuous
representative convention. General Tao construction, full adelic IW and full sampling theorems,
including the explicitly described rough/full-class/finite-quotient realization bridges, remain
independent unproved inputs. The earlier narrower endpoint results retain their own hypotheses.",

      "scope": "The full actual dyadic IW low maximum is proved at every real Q>=2^k, uniformly in the
cyclic measure of variation at most one and 0<beta<=1, for the real-Q geometric construction and for all
 integer lp inputs at p_r. The width, denominator bound and logarithmic cost are the literal real-Q
quantities. A single harmless enlargement of the universal parameter constant from C to C^2 is made
once. The arithmetic set, period, rational coverage through Q, denominator bound and goodness are
retained; the maximal estimate uses exactly that set, period and real-Q cutoff. The adjusted-base proof
and cost comparison are checked, as are all own symbol, smoothness, sampling, short-scale, narrow,
remainder and all-input extension steps. The independent general standard inputs remain explicit; no
current-paper conclusion is an external assumption.",

      "scope": "Complete printed Corollary7.46 as an implication of the explicit independent inputs, for
 all three actual families and every invertible measure-preserving probability system. One common C >= 1
 serves the strong exponential rate and source Orlicz gauge; one common modular multiplier is fixed
before all systems, families, functions and levels. Every 1 < p <= 2 has the actual strong maximal norm
with almost-everywhere finiteness and actual Lp membership. The proper extended maximum satisfies the
source modular inequality. Every measurable Orlicz member at some positive scale has actual averages
converging almost everywhere and in L1 to the same genuine L1 limit, with integrability of every average
 and both L1 seminorm/integral-norm convergence checked. Own truncation, rescaling, Cauchy/density, L1
operator and limit-identification deductions are proved. At checkpoint1264 the current public export
consumes the proved finite signed maximal theorem at constant6; a supplied RawFiniteSignedMaximalInput
and its constant R are no longer hypotheses.",
      "remaining": "No remaining printed clause within the agreed conditional-formalization scope. The
independent general Calderon strong/modular and bounded-class polynomial convergence inputs, including
their unproved published-theorem/normalization bridges, remain explicit, as do the earlier Theorem7.2
independent inputs. Stronger standalone Section7 auxiliary ranges remain separately partial.",

      "prior_scope_before_arithmetic_discharge": "The actual finite lower sifted set and primitive
prime-plus-prime-square representation set satisfy the exact cardinal inequality with error at most
omega(n-1). A uniform O_epsilon(N^epsilon) bound is proved with the source quantifiers. The use of r-1
rather than r is matched by an injective reindexing. The only extra input is the classical primitive
sum-of-two-squares criterion for m congruent2 modulo4. At1260: The Section9 final quantitative counting
endpoint was already complete conditionally at1259. This checkpoint proves the elementary
primitive-representation multiplication step from Mathlib Fermat and explicit finite-field algebra. The
full primitive two-square criterion and its consumption are the next obligations; no source claim is
newly promoted yet. The Section11 edits remain in progress, not assumed applied. At1261: Proved the full
 PrimitiveTwoSquaresCriterion from pinned Mathlib and elementary algebra, and proved W(alpha)
convergence/nonnegativity for every alpha>1. Constructed a concrete nonzero compactly supported smooth
seed. The next stage exports the Section9 arithmetic and headline statements without the former
criterion or seed hypotheses, then reconciles the stale Section9 map. User manuscript edits remain in
progress.",

newly promoted yet. The Section11 edits remain in progress, not assumed applied. At1261: Proved the full
 PrimitiveTwoSquaresCriterion from pinned Mathlib and elementary algebra, and proved W(alpha)
convergence/nonnegativity for every alpha>1. Constructed a concrete nonzero compactly supported smooth
seed. The next stage exports the Section9 arithmetic and headline statements without the former
criterion or seed hypotheses, then reconciles the stale Section9 map. User manuscript edits remain in
progress.",

      "scope": "The full source master sieve reduction is proved from ordinary source hypotheses and the
 adopted closed multiplier cutoff. Its exact finite error is at most2 omega(n-1), and its uniform
O(N^epsilon) consequence is exported. No primitive-criterion or analytic assumption is needed for this
arithmetic reduction. At1262: Every Section9 numbered source claim and its final quantitative theorem is
 complete in the agreed scope. All elementary arithmetic reductions are now proved without an extra
primitive two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is
 constructed. Only the explicit independent analytic inputs remain for the circle-method/sieve/headline
estimates. The user is applying previous manuscript edits; no application is assumed and original
sources are unchanged.",

      "corrected_source_deduction_complete": true,
      "prior_scope_before_arithmetic_discharge": "The master actual finite-set reduction is completely
assembled for the user-corrected closed-cutoff L, with error at most twice omega(n-1) and the full
uniform O_epsilon(N^epsilon) consequence. Its own truncated equality and upper bound are discharged by
the earlier proved modules. The independent classical primitive two-square criterion remains explicit.
At1260: The Section9 final quantitative counting endpoint was already complete conditionally at1259.
This checkpoint proves the elementary primitive-representation multiplication step from Mathlib Fermat
and explicit finite-field algebra. The full primitive two-square criterion and its consumption are the
next obligations; no source claim is newly promoted yet. The Section11 edits remain in progress, not
assumed applied. At1261: Proved the full PrimitiveTwoSquaresCriterion from pinned Mathlib and elementary
 algebra, and proved W(alpha) convergence/nonnegativity for every alpha>1. Constructed a concrete
nonzero compactly supported smooth seed. The next stage exports the Section9 arithmetic and headline
statements without the former criterion or seed hypotheses, then reconciles the stale Section9 map. User
 manuscript edits remain in progress.",

      ],
      "scope": "Complete source circle-method mean-square approximation for every A,delta>0, with
B0,C,K,N0 chosen before N and every arithmetic family. Covers all B>=B0, exact strict real
L<N^(2-delta), positive ell,k with k<V(ell), every coprime residue class, arbitrary complex coefficients
 of norm<=1, and all n<N^2. The stronger uniform cutoff statement holds for every 2<=U<=N,W>=2. The
final source theorem removes cutoffs using the proved equation-imposed bounds, and uses the actual
finite prime-pair count, actual local Euler factor G_R and actual autocorrelation singular integral H_R.
 Fourier inversion, all three error identifications, shared constants, minor estimate, major
replacement, arithmetic completion and smoothing are consumed internally. Its only unformalized
hypotheses are independent ordinary SW prime counts, ordinary unweighted BV prime-count distribution,
and uniform raw Ren/Ghosh quadratic estimates. No own-paper conclusion is assumed. At1212: Completed all
 Section10 source statements and the full circle-method implication; the three independent raw deep
inputs remain explicit and unproved. At1213: Completed every Section10 source statement and the full
source circle-method implication, including the original smooth compact seed and exact normalized
integral. Only the three agreed independent raw deep inputs remain for this circle-method implication.",
      "remaining": "None within the full source circle-method implication. The three independent raw
distribution/exponential-sum inputs remain unproved; Section11 and the headline Goldbach result remain
separate work.",

      "scope": "Full source lower-sieve proposition, including the actual representation sequence,
original X_n and Euler product, coefficients before n, a common error tending to zero, and the N^4(log
N)^(-A) mean-square remainder bound. The pointwise theorem holds throughout the source retained range
(indeed all n=12 mod24). General classical sieve/Mertens/function-continuity and ordinary
SW/BV/Ren-Ghosh inputs remain explicit and unproved. At1229: Common cutoff compatibility for the
circle-method and full lower-sieve estimates is proved for every requested lower bound on C; main-term
size remains to be joined. At1230: The full source main-term size and the entire lower-bound side are
complete conditionally, including an exponent independent of C, uniform smoothing, one common large
cutoff and finite error-to-exception deductions. At1230 the source main-term size and the full lower
sieve are proved jointly for the same C>=A0+6; finite positive-count and exceptional-cardinality
deductions are checked. At1258: All Section11 numbered claims are complete in the agreed conditional
scope for the explicitly supplied corrected presieving statement. The original weaker statement is not
proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one
cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic
mean-square saving. The final Goldbach theorem remains the next deduction.",

      "scope": "The full source upper sieve is complete in uniform epsilon form, with the exact c_(9/8)
F_1(2) W(9/8) coefficient, original actual main term and closed multiplier set. All coefficients precede
 n; source divisor counts, refined preliminary/outer dimensions, uniform varying levels, the shifted
double remainder sum, its circle-method embedding and the fixed-sieve O(N^(1/4)) correction are proved.
The total error has arbitrarily strong logarithmic mean-square saving. Only independent general SW, BV,
Ren/Ghosh, classical one-stage sieve, effective multiplicative mean and Mertens inputs and general sieve
 normalizations remain unproved; no own-paper endpoint is assumed. At1257: Full upper-sieve proposition
p:sieveneedupper8 complete in uniform epsilon form from explicit independent classical inputs, with the
exact coefficient and arbitrary logarithmic mean-square saving. The lower analytic estimate and both
remainder transports are available at a shared prescribed cutoff. The final joint Section11 assembly and
 manuscript synchronization are next. At1258: All Section11 numbered claims are complete in the agreed
conditional scope for the explicitly supplied corrected presieving statement. The original weaker
statement is not proved and must be replaced in the user manuscript. The complete joint lower/upper
estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary
combined logarithmic mean-square saving. The final Goldbach theorem remains the next deduction.",

      "scope": "Full source lemma proved for every A0>0 and every fixed C>=A0+6, uniformly over the
exact retained n range. The actual X_n Theta_n(z) is at least a positive constant times N(log
N)^(-(A0/2+6)); the exponent is independent of C. Actual archimedean, smoothing and local-product
arguments are proved; only the already recorded independent interval Mertens products remain external.
The same large C is joined to the complete lower sieve. At1258: All Section11 numbered claims are
complete in the agreed conditional scope for the explicitly supplied corrected presieving statement. The
 original weaker statement is not proved and must be replaced in the user manuscript. The complete joint
 lower/upper estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and
arbitrary combined logarithmic mean-square saving. The final Goldbach theorem remains the next
deduction.",

      "scope": "The actual W integral has the unconditional exact bound 8 sqrt(2) W(9/8)<=9/32, proved
by positive interval integration and exact rpow primitives. The strict comparison is proved for the
classical normalized sieve values f_(1/2)(9/8)=sqrt(8 exp(gamma)/(9 pi)) log2 and F_1(2)=exp(gamma).
Identifying the generic independent sieve functions with those classical normalized values remains
explicit, within GENERAL_SIEVE; the paper comparison is not assumed. No floating point evaluation or
unchecked evaluator is used. At1253: Proved the exact actual W integral bound, the normalized
half/linear sieve comparison and strict positivity. Classical sieve-function normalizations remain
explicit general input identities. The upper-sieve application and final Goldbach theorem remain open;
no paper endpoint is assumed. At1258: All Section11 numbered claims are complete in the agreed
conditional scope for the explicitly supplied corrected presieving statement. The original weaker
statement is not proved and must be replaced in the user manuscript. The complete joint lower/upper
estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary
combined logarithmic mean-square saving. The final Goldbach theorem remains the next deduction.",

      ],
      "scope": " At1176: The actual normalized autocorrelation cutoff has a proved positive denominator,
 exact convolution integral, eta(0)=1 and real nonnegative inverse Fourier transform. At1177: The scaled
 actual eta_N and its square have proved real nonnegative inverse Fourier transforms and exact compact
support inherited from the seed. At1178: The actual eta is real, even, bounded by1, has zero derivative
at0 and satisfies the full global quadratic source cutoff bound. At1179: Two-sided absolute
integrability and an explicit L1 estimate are proved from the exact finite-scale bound and
inverse-three-halves tail. At1180: The exact cutoff-weighted Fourier integral is a proved positive
average of the inverse kernel, with Fubini integrability discharged. At1181: The actual source singular
integral is proved real nonnegative, uniformly in all positive ell and every real n, including the
empty-domain branch. At1182: The actual Euclidean product and smoothed integrand are globally
integrable, and the exact source singular integral satisfies a proved uniform O(N) bound for all
positive ell. At1183: The full quantitative real-line smoothing error bound is proved with absolute
constant6 and every integrability condition discharged. At1184: The actual smoothed and unsmoothed
source integrals satisfy the full uniform O(N/sqrt(R)) comparison, with all integrability and
empty-domain branches proved. At1185: The actual quadratic affine density is globally integrable and has
 the proved exact product Fourier transform, including the scale factor. At1186: The genuine logarithmic
 quadratic density is continuous and integrable, with its exact source product Fourier transform proved
and endpoint exceptional sets checked. At1187: The full source l:positiveH9 is proved: the exact
autocorrelation cutoff, real nonnegative smoothed singular integral, its exact printed one-variable
H_ell domain, and the uniform O(N/sqrt(R)) comparison, including all positive ell and empty-domain
cases. There is no independent analytic input for this lemma. At1213: Completed every Section10 source
statement and the full source circle-method implication, including the original smooth compact seed and
exact normalized integral. Only the three agreed independent raw deep inputs remain for this
circle-method implication.",
      "remaining": "None. Positivity and the comparison with the exact printed one-variable domain are
proved for the actual source cutoff and integrals, without extra external analytic input.",

      "scope": " At1126: The exact lcm-fibre divisor bound and weighted progression-error reindexing for
 the major arcs are proved. At1137: Exact strict-cutoff reduction and a uniform one-term endpoint error
are proved for the actual progression sums. At1138: The exact prime counting and logarithmic-integral
progression models, derivatives and lower-endpoint identities are proved. At1139: The actual prime-count
 discrepancy is transported through every smooth unit phase with an explicit quantitative error,
including the lower prime endpoint. At1140: Exact positive-phase linear and quadratic partial-summation
errors are proved from ordinary prime-counting discrepancies, with signs and totient normalizations
checked. At1141: The actual prime-square major-arc model and explicit nonunit/count-discrepancy error
are proved with the exact source sign and normalization. At1142: The fixed-q lcm fibre bound and
complete reduction to ordinary unweighted modulus-distribution errors are proved. At1143: The compatible
 lcm residue sets, q-cardinality bound and generalized CRT existence/converse are proved for arbitrary
positive moduli. At1144: The exact Upsilon coefficient for the actual compatible lcm residue classes is
proved, including both signs and totient factors. At1145: The exact independent ordinary prime-count
SW/BV boundaries are implemented; real-error equivalence, square-model numeric bound and logarithmic
absorption are proved. At1146: The full uniform source SW prime-square major approximation is a complete
 deduction from the independent ordinary prime-count SW input. At1147: Exact prime progression residue
fibres and positive rational-phase grouping are proved for the actual finite sums. At1148: The actual
source linear model and all nonunit/strict-endpoint errors are proved from ordinary lcm-modulus
prime-count discrepancies. At1149: The actual strict source J integral, clamped prime cutoff, and
uniform numeric linear model error are matched exactly. At1150: Actual BV row approximation is proved
under the independent ordinary unweighted BV input, with individual progression cutoffs and all finite
exceptional terms retained. At1151: The printed source ranges imply the ordinary BV level and comparable
 logarithmic saving, with a threshold uniform in every active ell. At1152: The actual source row-scale
sum and coefficient-family cardinality square bound are proved, including all empty-cutoff cases.
At1153: Every retained prime endpoint/nonunit term is absorbed uniformly from the exact printed source
ranges, using a proved power saving. At1154: The full uniform source BV progression-error norm sum is
complete under the independent ordinary unweighted BV input, with all individual cutoffs and finite
errors included. At1155: Exact source major-set geometry, normalized measure, wrap-around lifts,
pairwise disjointness and eventual separation are proved. At1156: Measurable local coordinates and
genuine Euclidean model regularity and norm bounds are proved for the circle Bessel assembly. At1157:
The exact source major models are constructed on the circle, with proved localization and all-Lp
regularity and the required square size bound. At1158: Both full SW/BV major estimates now hold for the
constructed exact source circle models, uniformly in every printed parameter. At1159: The restricted
measurable Bessel inequalities and two-model major-arc mean-square assembly are proved. At1160: The
actual weighted source coefficient identity, model Lp bounds and complete logarithmic mean-square budget
 are proved. At1161: The full source major-arc mean-square approximation l:majorapproximation9 is
complete under ordinary SW and BV, uniformly in all printed data, with strict endpoints and finite
errors discharged.",

      "scope": "Completed Section 3 identities are reusable; this full statement is not counted as
partial merely because it cites them. At1162: The actual inclusive R-smooth arithmetic series is
absolutely summable, equals the source finite Euler product and admits an exact finite cutoff/tail
split. At1163: The genuine Euclidean source integrals have proved quadratic and linear frequency decay,
with explicit constants and all cutoffs retained. At1164: Unconditional reciprocal-totient harmonic
estimates, including arbitrary divisor progressions, and the exact gcd divisor expansion are proved.
At1165: The full source arithmetic-family harmonic estimate is proved unconditionally with explicit
divisor exponent2 and constant9 exp(2). At1166: Exact arbitrary-multiplier coefficient identities and
the uniform odd-prime bound8 gcd(p,k*ell)/p are proved. At1168: The genuine coefficient has a uniform
prime-power gcd bound, with every two-adic exponent handled explicitly. At1169: General-modulus source
coefficient decay tau(q)^9 gcd(q,k*ell)/q and principal Gauss decay tau(q)^3/sqrt(q) are proved
unconditionally. At1170: The actual weighted source arithmetic-family and finite denominator-tail bounds
 are proved; the full source arithmetic and completion lemmas remain open with explicit remaining
clauses. At1171: Normalized finite unit averages are proved invariant under reduction to every divisor
modulus. At1172: Primitive progression exponential cancellation and the coprime norm bound are proved
from actual finite unit sums. At1173: The actual Upsilon coefficient is an exact lcm-unit expectation
and satisfies exact simultaneous frequency/denominator reduction. At1174: The actual Upsilon coefficient
 has the proved sharp gcd/divisor decay tau(q) gcd(q,k*ell)/q. At1175: The full source
arithmetic-coefficient lemma is proved: absolute convergence, the all-prime infinite local Euler series
and its exact source G_R value, all three individual bounds with the common divisor exponent9, and the
complete real-cutoff harmonic family estimate. There are no external inputs for this lemma.",
```

      "scope": "Complete actual source major-completion mean-square estimate for every A,delta>0, all
sufficiently large C, all B>=0 and sufficiently large N, exact strict real arithmetic cutoffs, arbitrary
 coprime residue representatives and coefficients of norm at most one, and every 2<=U<=N,W>=2. Constants
 and thresholds precede N and all families. The actual major models, Euler factor G_R and singular
integral H_R are used. The sharp cutoff comparison, separated additional denominators, finite arithmetic
 completion and quantitative Rankin tail are proved internally. No independent deep input is used. The
source W<=N^2 restriction is unnecessary. The proof uses a weaker intermediate power of R that yields
the same prescribed logarithmic saving after increasing C. At1211: Completed the full source
major-completion lemma without external deep inputs.",
      "remaining": "None within the source major-completion statement. The independent SW/BV replacement
 and Ren/Ghosh estimates belong to separate lemmas.",

      "scope": " At1216: Proved the exact lower sieve sequence/progression count and its actual
circle-method remainder decomposition. The full fixed-sieve comparison remains proved; local densities
and later sieve conclusions remain open. At1219: Actual unit-square root counts, both candidate
prime-density bounds including p=5, and the explicit multiplicative sieve function are proved without
deep inputs. Full local-density normalization is the next internal obligation. At1220: Proved the
conductor-sensitive coefficient identity, all actual prime-factor cases, the exact factors at2 and3,
residue invariance, and normalized prime adjunction without division by the global base factor. Full
local-density source closure is reserved for the final product and CRT assembly. At1221: complete actual
 normalized Euler-product factorization, exact source CRT residues, inclusive prime cutoff,
multiplicativity and all density bounds are proved without external inputs. The upper base factor may
vanish; no division by it is used. At1221: Both full source local-density lemmas are proved without new
external inputs: exact original Euler normalization, inclusive cutoff, lower quotient identification,
source CRT specializations, upper multiplicativity and p=5, with common zero upper base factors
retained. Presieving and the later sieve estimates remain open.",
      "remaining": "None within the source statement and retained admissible context.",

      "scope": " At1217: Proved the exact upper sieve sequence/progression count, including all prime
exclusions, source multiplier arithmetic and residue independence from n. Local-density factorization
and the later analytic sieve estimates remain open. At1219: Actual unit-square root counts, both
candidate prime-density bounds including p=5, and the explicit multiplicative sieve function are proved
without deep inputs. Full local-density normalization is the next internal obligation. At1220: Proved
the conductor-sensitive coefficient identity, all actual prime-factor cases, the exact factors at2 and3,
 residue invariance, and normalized prime adjunction without division by the global base factor. Full
local-density source closure is reserved for the final product and CRT assembly. At1221: complete actual
 normalized Euler-product factorization, exact source CRT residues, inclusive prime cutoff,
multiplicativity and all density bounds are proved without external inputs. The upper base factor may
vanish; no division by it is used. At1221: Both full source local-density lemmas are proved without new
external inputs: exact original Euler normalization, inclusive cutoff, lower quotient identification,
source CRT specializations, upper multiplicativity and p=5, with common zero upper base factors
retained. Presieving and the later sieve estimates remain open.",
      "remaining": "None within the source statement and retained admissible context.",

      "scope": "The corrected two-range presieving statement is a complete implication from the explicit
 independent general one-stage sieve inputs. The exact source matched is the separately supplied
Section11_Reconciled.tex: X>=0, g(1)=1, fixed R=(log N)^C, R+1<=z<=D1<=N^A, refined1+K/logw dimension
bounds, and the preliminary endpointR+1. Coefficients precede the density/sequence and n, have absolute
value<=1 and exact level support; the common relative error tends to zero. The literal original weaker
manuscript statement is not claimed proved; replacement is required in the user manuscript. No original
source file was changed. At1258: All Section11 numbered claims are complete in the agreed conditional
scope for the explicitly supplied corrected presieving statement. The original weaker statement is not
proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one
cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic
mean-square saving. The final Goldbach theorem remains the next deduction. At1265 the uploaded
human-readable statement is reviewed directly: D0<D follows from its level chain, and the inline
interval prime conditions are proved equivalent in Lean. The corrected mathematical hypotheses are
verified as present in the actual upload; no presieving replacement remains outstanding.",

      ],
      "scope": "Complete source weighted upper main-term comparison, in uniform epsilon form, with the
actual multiplier set, local factors, finite Euler products and singular integrals. For every A>0, every
 fixed C>=A+24 and eta>0, one threshold in N works for all n=12 mod24 with N^2(log N)^(-A)<=n<N^2. The
coefficient is exactly c_(9/8) W(9/8)+eta. Strong multiplicativity, the uniform mean instantiation, both
 finite Abel arguments, W identity, all small-denominator and endpoint terms, moving logarithms,
integration, smoothing and relative errors are proved. Only the independent generic effective mean-value
 corollary and classical fixed-progression Mertens bounds remain explicit unproved hypotheses. The
source lemma statement is unchanged; two proof replacements are supplied but not applied. At1252: The
full source weighted upper main-term comparison l:wumatomakisum is complete as a checked implication
from independent generic effective mean-value and classical Mertens inputs, with the exact printed
constant, actual source definitions, uniform retained-range quantifiers, and every summation,
integration and relative-error obligation discharged.",

      "scope": "All four source clauses are complete conditional implications for one common
construction at every real Q>=2^k, r>=2 and k>=4. The literal B, epsilon and C_rk are retained; P<=3^Q,
every a/q modulo one with q<=Q, all denominator bounds and full goodness are proved. The rough
multiplier conclusion is an actual bounded operator on the entire integer lp space, with the exact
finite-convolution Fourier kernel, uniqueness and norm <=C_rk times the actual full real Lp operator
norm. The general full-Lp real/cyclic product bound and rank-one coefficient factorization are proved.
Both major-arc sampling directions, actual unique interpolation on the full distributional integer lp
Fourier-support class, the inverse-C_rk source inequality, and all finite-dimensional normed complex
Shannon targets throughout 1<=p<=infinity are retained. Point sampling uses the standard continuous
representative convention. General Tao construction, full adelic IW and full sampling theorems,
including the explicitly described rough/full-class/finite-quotient realization bridges, remain
independent unproved inputs. The earlier narrower endpoint results retain their own hypotheses.",

      "scope": "Both parts are complete conditional implications. Part(i): the actual enumerated prime
squares are persistently universally L1-bad on every truly nonatomic ergodic measure-preserving
probability system, with every infinite cutoff set and an actual measurable positive-measure divergence
set. CRT, Dirichlet representation, correlation counts, large-prime block construction, all
moment/thickening/difference limits, uniform square-root fibers and the fixed-progression PNT
pushforward are proved. The original badness theorem, Sawyer, Conze, general Weil and fixed-progression
PNT remain separate unproved general inputs. Granville\u2013Kurlberg is not used by part(i). A checked
moment proof replaces the source strict finite-fraction argument, which has an exact kernel
counterexample. Part(ii) is a complete conditional implication: an absolute positive constant before
every invertible measure-preserving probability system, every 1 < p <= 2 and every Lp input; the proper
actual maximum over the first m prime squares for all m >= 1 is finite almost everywhere, belongs to Lp
and has the exact displayed exponential norm bound. The prime-counting/enumeration normalization, finite
 sums, first-prime case and equality of both full maxima are proved with no PNT or enumeration input.
The proof uses the already proved Corollary7.6 and the precise independent general strong Calderon
input, plus the earlier Theorem7.2 independent inputs. It does not use the bounded-class convergence
input. At checkpoint1264 the current public export consumes the proved finite signed maximal theorem at
constant6; a supplied RawFiniteSignedMaximalInput and its constant R are no longer hypotheses.",
      "remaining": "No remaining source clause within the agreed conditional scope. General inputs and
their exact convention bridges remain unproved. The user confirmed the three Section8 edits; the
selected project manuscript now contains the agreed moment proof.",

        "blueprint/Checkpoint_1262_GoldbachSectionNineComplete.md"
      ],
      "scope": "The full quantitative exceptional-set theorem is complete: for every A>0, the actual
exceptional set of positive n<X congruent12 mod24 without a prime plus a square-of-prime representation
whose first prime is a primitive sum of two squares plus1 has size O_A(X(log X)^(-A)), eventually at
every real X. The representation and exceptional-set membership are exact. The common-cutoff Section11
estimates, positive numerical gap, arbitrary logarithmic mean-square saving, all arithmetic losses,
small n and the passage from N^2 to real X are discharged. Explicit independent general SW, BV,
Ren/Ghosh, one-stage sieve, effective multiplicative mean, Mertens, normalized sieve values/continuity
and primitive two-square criterion remain unproved theorem parameters. No own-paper endpoint is a
hypothesis. At1259: Section11 and the final quantitative Goldbach theorem are complete in the agreed
conditional scope, using the supplied corrected presieving statement. Every paper endpoint is
discharged; only explicit independent general classical inputs and their normalizations remain unproved.
 Original manuscripts are unchanged and the supplied Section11 replacements still require user
application. No additional completion credit is claimed for stronger unnumbered assertions in alternate
proof routes. At1261: Proved the full PrimitiveTwoSquaresCriterion from pinned Mathlib and elementary
algebra, and proved W(alpha) convergence/nonnegativity for every alpha>1. Constructed a concrete nonzero
 compactly supported smooth seed. The next stage exports the Section9 arithmetic and headline statements
 without the former criterion or seed hypotheses, then reconciles the stale Section9 map. User
manuscript edits remain in progress. At1262 the final endpoint is exported from GoldbachSection11Inputs
alone: the primitive two-square criterion is proved internally and a fixed nonzero smooth compact seed
is constructed. The real-X bound and zero exceptional density need no separate arithmetic or seed
assumption. At1262: Every Section9 numbered source claim and its final quantitative theorem is complete
in the agreed scope. All elementary arithmetic reductions are now proved without an extra primitive
two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is
constructed. Only the explicit independent analytic inputs remain for the circle-method/sieve/headline
estimates. The user is applying previous manuscript edits; no application is assumed and original
sources are unchanged.",

        "blueprint/Checkpoint_1213_GoldbachCircleSourceSeed.md"
      ],
      "scope": "Complete source circle-method mean-square approximation for every A,delta>0, with
B0,C,K,N0 chosen before N and every arithmetic family. Covers all B>=B0, exact strict real
L<N^(2-delta), positive ell,k with k<V(ell), every coprime residue class, arbitrary complex coefficients
 of norm<=1, and all n<N^2. The stronger uniform cutoff statement holds for every 2<=U<=N,W>=2. The
final source theorem removes cutoffs using the proved equation-imposed bounds, and uses the actual
finite prime-pair count, actual local Euler factor G_R and actual autocorrelation singular integral H_R.
 Fourier inversion, all three error identifications, shared constants, minor estimate, major
replacement, arithmetic completion and smoothing are consumed internally. Its only unformalized
hypotheses are independent ordinary SW prime counts, ordinary unweighted BV prime-count distribution,
and uniform raw Ren/Ghosh quadratic estimates. No own-paper conclusion is assumed. At1212: Completed all
 Section10 source statements and the full circle-method implication; the three independent raw deep
inputs remain explicit and unproved. At1213: Completed every Section10 source statement and the full
source circle-method implication, including the original smooth compact seed and exact normalized
```

```
integral. Only the three agreed independent raw deep inputs remain for this circle-method implication.",
      "remaining": "None within the full source circle-method implication. The three independent raw
distribution/exponential-sum inputs remain unproved; Section11 and the headline Goldbach result remain
separate work.",

      ],
      "scope": "Full source lower-sieve proposition, including the actual representation sequence,
original X_n and Euler product, coefficients before n, a common error tending to zero, and the N^4(log
N)^(-A) mean-square remainder bound. The pointwise theorem holds throughout the source retained range
(indeed all n=12 mod24). General classical sieve/Mertens/function-continuity and ordinary
SW/BV/Ren-Ghosh inputs remain explicit and unproved. At1229: Common cutoff compatibility for the
circle-method and full lower-sieve estimates is proved for every requested lower bound on C; main-term
size remains to be joined. At1230: The full source main-term size and the entire lower-bound side are
complete conditionally, including an exponent independent of C, uniform smoothing, one common large
cutoff and finite error-to-exception deductions. At1230 the source main-term size and the full lower
sieve are proved jointly for the same C>=A0+6; finite positive-count and exceptional-cardinality
deductions are checked. At1258: All Section11 numbered claims are complete in the agreed conditional
scope for the explicitly supplied corrected presieving statement. The original weaker statement is not
proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one
cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic
mean-square saving. The final Goldbach theorem remains the next deduction.",

      "scope": "The full source upper sieve is complete in uniform epsilon form, with the exact c_(9/8)
F_1(2) W(9/8) coefficient, original actual main term and closed multiplier set. All coefficients precede
 n; source divisor counts, refined preliminary/outer dimensions, uniform varying levels, the shifted
double remainder sum, its circle-method embedding and the fixed-sieve O(N^(1/4)) correction are proved.
The total error has arbitrarily strong logarithmic mean-square saving. Only independent general SW, BV,
Ren/Ghosh, classical one-stage sieve, effective multiplicative mean and Mertens inputs and general sieve
 normalizations remain unproved; no own-paper endpoint is assumed. At1257: Full upper-sieve proposition
p:sieveneedupper8 complete in uniform epsilon form from explicit independent classical inputs, with the
exact coefficient and arbitrary logarithmic mean-square saving. The lower analytic estimate and both
remainder transports are available at a shared prescribed cutoff. The final joint Section11 assembly and
 manuscript synchronization are next. At1258: All Section11 numbered claims are complete in the agreed
conditional scope for the explicitly supplied corrected presieving statement. The original weaker
statement is not proved and must be replaced in the user manuscript. The complete joint lower/upper
estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary
combined logarithmic mean-square saving. The final Goldbach theorem remains the next deduction.",

      "scope": " At1176: The actual normalized autocorrelation cutoff has a proved positive denominator,
 exact convolution integral, eta(0)=1 and real nonnegative inverse Fourier transform. At1177: The scaled
 actual eta_N and its square have proved real nonnegative inverse Fourier transforms and exact compact
support inherited from the seed. At1178: The actual eta is real, even, bounded by1, has zero derivative
at0 and satisfies the full global quadratic source cutoff bound. At1179: Two-sided absolute
integrability and an explicit L1 estimate are proved from the exact finite-scale bound and
inverse-three-halves tail. At1180: The exact cutoff-weighted Fourier integral is a proved positive
average of the inverse kernel, with Fubini integrability discharged. At1181: The actual source singular
integral is proved real nonnegative, uniformly in all positive ell and every real n, including the
empty-domain branch. At1182: The actual Euclidean product and smoothed integrand are globally
integrable, and the exact source singular integral satisfies a proved uniform O(N) bound for all
positive ell. At1183: The full quantitative real-line smoothing error bound is proved with absolute
constant6 and every integrability condition discharged. At1184: The actual smoothed and unsmoothed
source integrals satisfy the full uniform O(N/sqrt(R)) comparison, with all integrability and
empty-domain branches proved. At1185: The actual quadratic affine density is globally integrable and has
 the proved exact product Fourier transform, including the scale factor. At1186: The genuine logarithmic
 quadratic density is continuous and integrable, with its exact source product Fourier transform proved
and endpoint exceptional sets checked. At1187: The full source l:positiveH9 is proved: the exact
autocorrelation cutoff, real nonnegative smoothed singular integral, its exact printed one-variable
H_ell domain, and the uniform O(N/sqrt(R)) comparison, including all positive ell and empty-domain
cases. There is no independent analytic input for this lemma. At1213: Completed every Section10 source
statement and the full source circle-method implication, including the original smooth compact seed and
exact normalized integral. Only the three agreed independent raw deep inputs remain for this
circle-method implication.",
      "remaining": "None. Positivity and the comparison with the exact printed one-variable domain are
proved for the actual source cutoff and integrals, without extra external analytic input.",

      ],
      "scope": " At1126: The exact lcm-fibre divisor bound and weighted progression-error reindexing for
 the major arcs are proved. At1137: Exact strict-cutoff reduction and a uniform one-term endpoint error
are proved for the actual progression sums. At1138: The exact prime counting and logarithmic-integral
progression models, derivatives and lower-endpoint identities are proved. At1139: The actual prime-count
 discrepancy is transported through every smooth unit phase with an explicit quantitative error,
including the lower prime endpoint. At1140: Exact positive-phase linear and quadratic partial-summation
errors are proved from ordinary prime-counting discrepancies, with signs and totient normalizations
checked. At1141: The actual prime-square major-arc model and explicit nonunit/count-discrepancy error
are proved with the exact source sign and normalization. At1142: The fixed-q lcm fibre bound and
complete reduction to ordinary unweighted modulus-distribution errors are proved. At1143: The compatible
 lcm residue sets, q-cardinality bound and generalized CRT existence/converse are proved for arbitrary
positive moduli. At1144: The exact Upsilon coefficient for the actual compatible lcm residue classes is
proved, including both signs and totient factors. At1145: The exact independent ordinary prime-count
SW/BV boundaries are implemented; real-error equivalence, square-model numeric bound and logarithmic
absorption are proved. At1146: The full uniform source SW prime-square major approximation is a complete
 deduction from the independent ordinary prime-count SW input. At1147: Exact prime progression residue
fibres and positive rational-phase grouping are proved for the actual finite sums. At1148: The actual
source linear model and all nonunit/strict-endpoint errors are proved from ordinary lcm-modulus
prime-count discrepancies. At1149: The actual strict source J integral, clamped prime cutoff, and
uniform numeric linear model error are matched exactly. At1150: Actual BV row approximation is proved
under the independent ordinary unweighted BV input, with individual progression cutoffs and all finite
exceptional terms retained. At1151: The printed source ranges imply the ordinary BV level and comparable
 logarithmic saving, with a threshold uniform in every active ell. At1152: The actual source row-scale
sum and coefficient-family cardinality square bound are proved, including all empty-cutoff cases.
At1153: Every retained prime endpoint/nonunit term is absorbed uniformly from the exact printed source
ranges, using a proved power saving. At1154: The full uniform source BV progression-error norm sum is
complete under the independent ordinary unweighted BV input, with all individual cutoffs and finite
errors included. At1155: Exact source major-set geometry, normalized measure, wrap-around lifts,
pairwise disjointness and eventual separation are proved. At1156: Measurable local coordinates and
genuine Euclidean model regularity and norm bounds are proved for the circle Bessel assembly. At1157:
The exact source major models are constructed on the circle, with proved localization and all-Lp
regularity and the required square size bound. At1158: Both full SW/BV major estimates now hold for the
constructed exact source circle models, uniformly in every printed parameter. At1159: The restricted
measurable Bessel inequalities and two-model major-arc mean-square assembly are proved. At1160: The
actual weighted source coefficient identity, model Lp bounds and complete logarithmic mean-square budget
 are proved. At1161: The full source major-arc mean-square approximation l:majorapproximation9 is
complete under ordinary SW and BV, uniformly in all printed data, with strict endpoints and finite
errors discharged.",
      "remaining": "No unmatched clause remains in this lemma. The independent ordinary SW and BV proofs
 remain external; apply docs/MAJOR_ARC_PROOF_REPLACEMENT.tex to correct the endpoint bookkeeping in its
source proof.",

      "scope": "Completed Section 3 identities are reusable; this full statement is not counted as
partial merely because it cites them. At1162: The actual inclusive R-smooth arithmetic series is
absolutely summable, equals the source finite Euler product and admits an exact finite cutoff/tail
split. At1163: The genuine Euclidean source integrals have proved quadratic and linear frequency decay,
with explicit constants and all cutoffs retained. At1164: Unconditional reciprocal-totient harmonic
estimates, including arbitrary divisor progressions, and the exact gcd divisor expansion are proved.
At1165: The full source arithmetic-family harmonic estimate is proved unconditionally with explicit
divisor exponent2 and constant9 exp(2). At1166: Exact arbitrary-multiplier coefficient identities and
the uniform odd-prime bound8 gcd(p,k*ell)/p are proved. At1168: The genuine coefficient has a uniform
prime-power gcd bound, with every two-adic exponent handled explicitly. At1169: General-modulus source
coefficient decay tau(q)^9 gcd(q,k*ell)/q and principal Gauss decay tau(q)^3/sqrt(q) are proved
unconditionally. At1170: The actual weighted source arithmetic-family and finite denominator-tail bounds
 are proved; the full source arithmetic and completion lemmas remain open with explicit remaining
clauses. At1171: Normalized finite unit averages are proved invariant under reduction to every divisor
modulus. At1172: Primitive progression exponential cancellation and the coprime norm bound are proved
from actual finite unit sums. At1173: The actual Upsilon coefficient is an exact lcm-unit expectation
and satisfies exact simultaneous frequency/denominator reduction. At1174: The actual Upsilon coefficient
 has the proved sharp gcd/divisor decay tau(q) gcd(q,k*ell)/q. At1175: The full source
arithmetic-coefficient lemma is proved: absolute convergence, the all-prime infinite local Euler series
and its exact source G_R value, all three individual bounds with the common divisor exponent9, and the
complete real-cutoff harmonic family estimate. There are no external inputs for this lemma.",
      "remaining": "None. All clauses are proved under the source hypotheses; no extra external
mathematical input.",
      "external_inputs": []

      "scope": "Complete actual source major-completion mean-square estimate for every A,delta>0, all
sufficiently large C, all B>=0 and sufficiently large N, exact strict real arithmetic cutoffs, arbitrary
 coprime residue representatives and coefficients of norm at most one, and every 2<=U<=N,W>=2. Constants
 and thresholds precede N and all families. The actual major models, Euler factor G_R and singular
integral H_R are used. The sharp cutoff comparison, separated additional denominators, finite arithmetic
 completion and quantitative Rankin tail are proved internally. No independent deep input is used. The
source W<=N^2 restriction is unnecessary. The proof uses a weaker intermediate power of R that yields
the same prescribed logarithmic saving after increasing C. At1211: Completed the full source
major-completion lemma without external deep inputs.",
      "remaining": "None within the source major-completion statement. The independent SW/BV replacement
 and Ren/Ghosh estimates belong to separate lemmas.",

      "scope": "The corrected two-range presieving statement is a complete implication from the explicit
 independent general one-stage sieve inputs. The exact source matched is the separately supplied
Section11_Reconciled.tex: X>=0, g(1)=1, fixed R=(log N)^C, R+1<=z<=D1<=N^A, refined1+K/logw dimension
bounds, and the preliminary endpointR+1. Coefficients precede the density/sequence and n, have absolute
value<=1 and exact level support; the common relative error tends to zero. The literal original weaker
manuscript statement is not claimed proved; replacement is required in the user manuscript. No original
source file was changed. At1258: All Section11 numbered claims are complete in the agreed conditional
scope for the explicitly supplied corrected presieving statement. The original weaker statement is not
proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one
cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic
mean-square saving. The final Goldbach theorem remains the next deduction. At1265 the uploaded
human-readable statement is reviewed directly: D0<D follows from its level chain, and the inline
interval prime conditions are proved equivalent in Lean. The corrected mathematical hypotheses are
verified as present in the actual upload; no presieving replacement remains outstanding.",

      "scope": "Complete source circle-method mean-square approximation for every A,delta>0, with
B0,C,K,N0 chosen before N and every arithmetic family. Covers all B>=B0, exact strict real
L<N^(2-delta), positive ell,k with k<V(ell), every coprime residue class, arbitrary complex coefficients
 of norm<=1, and all n<N^2. The stronger uniform cutoff statement holds for every 2<=U<=N,W>=2. The
final source theorem removes cutoffs using the proved equation-imposed bounds, and uses the actual
finite prime-pair count, actual local Euler factor G_R and actual autocorrelation singular integral H_R.
 Fourier inversion, all three error identifications, shared constants, minor estimate, major
replacement, arithmetic completion and smoothing are consumed internally. Its only unformalized
hypotheses are independent ordinary SW prime counts, ordinary unweighted BV prime-count distribution,
and uniform raw Ren/Ghosh quadratic estimates. No own-paper conclusion is assumed. At1212: Completed all
 Section10 source statements and the full circle-method implication; the three independent raw deep
inputs remain explicit and unproved. At1213: Completed every Section10 source statement and the full
source circle-method implication, including the original smooth compact seed and exact normalized
integral. Only the three agreed independent raw deep inputs remain for this circle-method implication.",

      "scope": "Full source lower-sieve proposition, including the actual representation sequence,
original X_n and Euler product, coefficients before n, a common error tending to zero, and the N^4(log
N)^(-A) mean-square remainder bound. The pointwise theorem holds throughout the source retained range
(indeed all n=12 mod24). General classical sieve/Mertens/function-continuity and ordinary
SW/BV/Ren-Ghosh inputs remain explicit and unproved. At1229: Common cutoff compatibility for the
circle-method and full lower-sieve estimates is proved for every requested lower bound on C; main-term
size remains to be joined. At1230: The full source main-term size and the entire lower-bound side are
complete conditionally, including an exponent independent of C, uniform smoothing, one common large
cutoff and finite error-to-exception deductions. At1230 the source main-term size and the full lower
sieve are proved jointly for the same C>=A0+6; finite positive-count and exceptional-cardinality
deductions are checked. At1258: All Section11 numbered claims are complete in the agreed conditional
scope for the explicitly supplied corrected presieving statement. The original weaker statement is not
proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one
cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic
mean-square saving. The final Goldbach theorem remains the next deduction.",

      ],
      "scope": "Complete source circle-method mean-square approximation for every A,delta>0, with
B0,C,K,N0 chosen before N and every arithmetic family. Covers all B>=B0, exact strict real
L<N^(2-delta), positive ell,k with k<V(ell), every coprime residue class, arbitrary complex coefficients
 of norm<=1, and all n<N^2. The stronger uniform cutoff statement holds for every 2<=U<=N,W>=2. The
final source theorem removes cutoffs using the proved equation-imposed bounds, and uses the actual
finite prime-pair count, actual local Euler factor G_R and actual autocorrelation singular integral H_R.
 Fourier inversion, all three error identifications, shared constants, minor estimate, major
replacement, arithmetic completion and smoothing are consumed internally. Its only unformalized
hypotheses are independent ordinary SW prime counts, ordinary unweighted BV prime-count distribution,
and uniform raw Ren/Ghosh quadratic estimates. No own-paper conclusion is assumed. At1212: Completed all
 Section10 source statements and the full circle-method implication; the three independent raw deep
inputs remain explicit and unproved. At1213: Completed every Section10 source statement and the full
source circle-method implication, including the original smooth compact seed and exact normalized
integral. Only the three agreed independent raw deep inputs remain for this circle-method implication.",

      "scope": "Full source lower-sieve proposition, including the actual representation sequence,
original X_n and Euler product, coefficients before n, a common error tending to zero, and the N^4(log
N)^(-A) mean-square remainder bound. The pointwise theorem holds throughout the source retained range
(indeed all n=12 mod24). General classical sieve/Mertens/function-continuity and ordinary
SW/BV/Ren-Ghosh inputs remain explicit and unproved. At1229: Common cutoff compatibility for the
circle-method and full lower-sieve estimates is proved for every requested lower bound on C; main-term
size remains to be joined. At1230: The full source main-term size and the entire lower-bound side are
complete conditionally, including an exponent independent of C, uniform smoothing, one common large
cutoff and finite error-to-exception deductions. At1230 the source main-term size and the full lower
sieve are proved jointly for the same C>=A0+6; finite positive-count and exceptional-cardinality
deductions are checked. At1258: All Section11 numbered claims are complete in the agreed conditional
scope for the explicitly supplied corrected presieving statement. The original weaker statement is not
proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one
cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic
mean-square saving. The final Goldbach theorem remains the next deduction.",

      "scope": "The full source upper sieve is complete in uniform epsilon form, with the exact c_(9/8)
F_1(2) W(9/8) coefficient, original actual main term and closed multiplier set. All coefficients precede
 n; source divisor counts, refined preliminary/outer dimensions, uniform varying levels, the shifted
double remainder sum, its circle-method embedding and the fixed-sieve O(N^(1/4)) correction are proved.
The total error has arbitrarily strong logarithmic mean-square saving. Only independent general SW, BV,
Ren/Ghosh, classical one-stage sieve, effective multiplicative mean and Mertens inputs and general sieve
 normalizations remain unproved; no own-paper endpoint is assumed. At1257: Full upper-sieve proposition
p:sieveneedupper8 complete in uniform epsilon form from explicit independent classical inputs, with the
exact coefficient and arbitrary logarithmic mean-square saving. The lower analytic estimate and both
remainder transports are available at a shared prescribed cutoff. The final joint Section11 assembly and
 manuscript synchronization are next. At1258: All Section11 numbered claims are complete in the agreed
conditional scope for the explicitly supplied corrected presieving statement. The original weaker
statement is not proved and must be replaced in the user manuscript. The complete joint lower/upper
estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary
combined logarithmic mean-square saving. The final Goldbach theorem remains the next deduction.",

      "scope": "All four source clauses are complete conditional implications for one common
construction at every real Q>=2^k, r>=2 and k>=4. The literal B, epsilon and C_rk are retained; P<=3^Q,
every a/q modulo one with q<=Q, all denominator bounds and full goodness are proved. The rough
multiplier conclusion is an actual bounded operator on the entire integer lp space, with the exact
finite-convolution Fourier kernel, uniqueness and norm <=C_rk times the actual full real Lp operator
norm. The general full-Lp real/cyclic product bound and rank-one coefficient factorization are proved.
Both major-arc sampling directions, actual unique interpolation on the full distributional integer lp
Fourier-support class, the inverse-C_rk source inequality, and all finite-dimensional normed complex
Shannon targets throughout 1<=p<=infinity are retained. Point sampling uses the standard continuous
representative convention. General Tao construction, full adelic IW and full sampling theorems,
including the explicitly described rough/full-class/finite-quotient realization bridges, remain
independent unproved inputs. The earlier narrower endpoint results retain their own hypotheses.",

      "scope": "Both parts are complete conditional implications. Part(i): the actual enumerated prime
squares are persistently universally L1-bad on every truly nonatomic ergodic measure-preserving
probability system, with every infinite cutoff set and an actual measurable positive-measure divergence
set. CRT, Dirichlet representation, correlation counts, large-prime block construction, all
moment/thickening/difference limits, uniform square-root fibers and the fixed-progression PNT
pushforward are proved. The original badness theorem, Sawyer, Conze, general Weil and fixed-progression
PNT remain separate unproved general inputs. Granville\u2013Kurlberg is not used by part(i). A checked
moment proof replaces the source strict finite-fraction argument, which has an exact kernel
counterexample. Part(ii) is a complete conditional implication: an absolute positive constant before
every invertible measure-preserving probability system, every 1 < p <= 2 and every Lp input; the proper
actual maximum over the first m prime squares for all m >= 1 is finite almost everywhere, belongs to Lp
and has the exact displayed exponential norm bound. The prime-counting/enumeration normalization, finite
 sums, first-prime case and equality of both full maxima are proved with no PNT or enumeration input.
The proof uses the already proved Corollary7.6 and the precise independent general strong Calderon
input, plus the earlier Theorem7.2 independent inputs. It does not use the bounded-class convergence
input. At checkpoint1264 the current public export consumes the proved finite signed maximal theorem at
constant6; a supplied RawFiniteSignedMaximalInput and its constant R are no longer hypotheses.",
      "remaining": "No remaining source clause within the agreed conditional scope. General inputs and
their exact convention bridges remain unproved. The user confirmed the three Section8 edits; the
selected project manuscript now contains the agreed moment proof.",

      ],
      "scope": "The full quantitative exceptional-set theorem is complete: for every A>0, the actual
exceptional set of positive n<X congruent12 mod24 without a prime plus a square-of-prime representation
whose first prime is a primitive sum of two squares plus1 has size O_A(X(log X)^(-A)), eventually at
every real X. The representation and exceptional-set membership are exact. The common-cutoff Section11
estimates, positive numerical gap, arbitrary logarithmic mean-square saving, all arithmetic losses,
small n and the passage from N^2 to real X are discharged. Explicit independent general SW, BV,
Ren/Ghosh, one-stage sieve, effective multiplicative mean, Mertens, normalized sieve values/continuity
and primitive two-square criterion remain unproved theorem parameters. No own-paper endpoint is a
hypothesis. At1259: Section11 and the final quantitative Goldbach theorem are complete in the agreed
conditional scope, using the supplied corrected presieving statement. Every paper endpoint is
discharged; only explicit independent general classical inputs and their normalizations remain unproved.
 Original manuscripts are unchanged and the supplied Section11 replacements still require user
application. No additional completion credit is claimed for stronger unnumbered assertions in alternate
proof routes. At1261: Proved the full PrimitiveTwoSquaresCriterion from pinned Mathlib and elementary
algebra, and proved W(alpha) convergence/nonnegativity for every alpha>1. Constructed a concrete nonzero
 compactly supported smooth seed. The next stage exports the Section9 arithmetic and headline statements
 without the former criterion or seed hypotheses, then reconciles the stale Section9 map. User
manuscript edits remain in progress. At1262 the final endpoint is exported from GoldbachSection11Inputs
alone: the primitive two-square criterion is proved internally and a fixed nonzero smooth compact seed
is constructed. The real-X bound and zero exceptional density need no separate arithmetic or seed
assumption. At1262: Every Section9 numbered source claim and its final quantitative theorem is complete
in the agreed scope. All elementary arithmetic reductions are now proved without an extra primitive
two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is
constructed. Only the explicit independent analytic inputs remain for the circle-method/sieve/headline
estimates. The user is applying previous manuscript edits; no application is assumed and original
sources are unchanged.",

      ],
      "scope": "Complete source circle-method mean-square approximation for every A,delta>0, with
B0,C,K,N0 chosen before N and every arithmetic family. Covers all B>=B0, exact strict real
L<N^(2-delta), positive ell,k with k<V(ell), every coprime residue class, arbitrary complex coefficients
 of norm<=1, and all n<N^2. The stronger uniform cutoff statement holds for every 2<=U<=N,W>=2. The
final source theorem removes cutoffs using the proved equation-imposed bounds, and uses the actual
finite prime-pair count, actual local Euler factor G_R and actual autocorrelation singular integral H_R.
 Fourier inversion, all three error identifications, shared constants, minor estimate, major
replacement, arithmetic completion and smoothing are consumed internally. Its only unformalized
hypotheses are independent ordinary SW prime counts, ordinary unweighted BV prime-count distribution,
and uniform raw Ren/Ghosh quadratic estimates. No own-paper conclusion is assumed. At1212: Completed all
 Section10 source statements and the full circle-method implication; the three independent raw deep
inputs remain explicit and unproved. At1213: Completed every Section10 source statement and the full
source circle-method implication, including the original smooth compact seed and exact normalized
```

```
integral. Only the three agreed independent raw deep inputs remain for this circle-method implication.",

      "scope": "Full source lower-sieve proposition, including the actual representation sequence,
original X_n and Euler product, coefficients before n, a common error tending to zero, and the N^4(log
N)^(-A) mean-square remainder bound. The pointwise theorem holds throughout the source retained range
(indeed all n=12 mod24). General classical sieve/Mertens/function-continuity and ordinary
SW/BV/Ren-Ghosh inputs remain explicit and unproved. At1229: Common cutoff compatibility for the
circle-method and full lower-sieve estimates is proved for every requested lower bound on C; main-term
size remains to be joined. At1230: The full source main-term size and the entire lower-bound side are
complete conditionally, including an exponent independent of C, uniform smoothing, one common large
cutoff and finite error-to-exception deductions. At1230 the source main-term size and the full lower
sieve are proved jointly for the same C>=A0+6; finite positive-count and exceptional-cardinality
deductions are checked. At1258: All Section11 numbered claims are complete in the agreed conditional
scope for the explicitly supplied corrected presieving statement. The original weaker statement is not
proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one
cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic
mean-square saving. The final Goldbach theorem remains the next deduction.",

      "scope": " At1176: The actual normalized autocorrelation cutoff has a proved positive denominator,
 exact convolution integral, eta(0)=1 and real nonnegative inverse Fourier transform. At1177: The scaled
 actual eta_N and its square have proved real nonnegative inverse Fourier transforms and exact compact
support inherited from the seed. At1178: The actual eta is real, even, bounded by1, has zero derivative
at0 and satisfies the full global quadratic source cutoff bound. At1179: Two-sided absolute
integrability and an explicit L1 estimate are proved from the exact finite-scale bound and
inverse-three-halves tail. At1180: The exact cutoff-weighted Fourier integral is a proved positive
average of the inverse kernel, with Fubini integrability discharged. At1181: The actual source singular
integral is proved real nonnegative, uniformly in all positive ell and every real n, including the
empty-domain branch. At1182: The actual Euclidean product and smoothed integrand are globally
integrable, and the exact source singular integral satisfies a proved uniform O(N) bound for all
positive ell. At1183: The full quantitative real-line smoothing error bound is proved with absolute
constant6 and every integrability condition discharged. At1184: The actual smoothed and unsmoothed
source integrals satisfy the full uniform O(N/sqrt(R)) comparison, with all integrability and
empty-domain branches proved. At1185: The actual quadratic affine density is globally integrable and has
 the proved exact product Fourier transform, including the scale factor. At1186: The genuine logarithmic
 quadratic density is continuous and integrable, with its exact source product Fourier transform proved
and endpoint exceptional sets checked. At1187: The full source l:positiveH9 is proved: the exact
autocorrelation cutoff, real nonnegative smoothed singular integral, its exact printed one-variable
H_ell domain, and the uniform O(N/sqrt(R)) comparison, including all positive ell and empty-domain
cases. There is no independent analytic input for this lemma. At1213: Completed every Section10 source
statement and the full source circle-method implication, including the original smooth compact seed and
exact normalized integral. Only the three agreed independent raw deep inputs remain for this
circle-method implication.",
      "remaining": "None. Positivity and the comparison with the exact printed one-variable domain are
proved for the actual source cutoff and integrals, without extra external analytic input.",

      ],
      "scope": " At1126: The exact lcm-fibre divisor bound and weighted progression-error reindexing for
 the major arcs are proved. At1137: Exact strict-cutoff reduction and a uniform one-term endpoint error
are proved for the actual progression sums. At1138: The exact prime counting and logarithmic-integral
progression models, derivatives and lower-endpoint identities are proved. At1139: The actual prime-count
 discrepancy is transported through every smooth unit phase with an explicit quantitative error,
including the lower prime endpoint. At1140: Exact positive-phase linear and quadratic partial-summation
errors are proved from ordinary prime-counting discrepancies, with signs and totient normalizations
checked. At1141: The actual prime-square major-arc model and explicit nonunit/count-discrepancy error
are proved with the exact source sign and normalization. At1142: The fixed-q lcm fibre bound and
complete reduction to ordinary unweighted modulus-distribution errors are proved. At1143: The compatible
 lcm residue sets, q-cardinality bound and generalized CRT existence/converse are proved for arbitrary
positive moduli. At1144: The exact Upsilon coefficient for the actual compatible lcm residue classes is
proved, including both signs and totient factors. At1145: The exact independent ordinary prime-count
SW/BV boundaries are implemented; real-error equivalence, square-model numeric bound and logarithmic
absorption are proved. At1146: The full uniform source SW prime-square major approximation is a complete
 deduction from the independent ordinary prime-count SW input. At1147: Exact prime progression residue
fibres and positive rational-phase grouping are proved for the actual finite sums. At1148: The actual
source linear model and all nonunit/strict-endpoint errors are proved from ordinary lcm-modulus
prime-count discrepancies. At1149: The actual strict source J integral, clamped prime cutoff, and
uniform numeric linear model error are matched exactly. At1150: Actual BV row approximation is proved
under the independent ordinary unweighted BV input, with individual progression cutoffs and all finite
exceptional terms retained. At1151: The printed source ranges imply the ordinary BV level and comparable
 logarithmic saving, with a threshold uniform in every active ell. At1152: The actual source row-scale
sum and coefficient-family cardinality square bound are proved, including all empty-cutoff cases.
At1153: Every retained prime endpoint/nonunit term is absorbed uniformly from the exact printed source
ranges, using a proved power saving. At1154: The full uniform source BV progression-error norm sum is
complete under the independent ordinary unweighted BV input, with all individual cutoffs and finite
errors included. At1155: Exact source major-set geometry, normalized measure, wrap-around lifts,
pairwise disjointness and eventual separation are proved. At1156: Measurable local coordinates and
genuine Euclidean model regularity and norm bounds are proved for the circle Bessel assembly. At1157:
The exact source major models are constructed on the circle, with proved localization and all-Lp
regularity and the required square size bound. At1158: Both full SW/BV major estimates now hold for the
constructed exact source circle models, uniformly in every printed parameter. At1159: The restricted
measurable Bessel inequalities and two-model major-arc mean-square assembly are proved. At1160: The
actual weighted source coefficient identity, model Lp bounds and complete logarithmic mean-square budget
 are proved. At1161: The full source major-arc mean-square approximation l:majorapproximation9 is
complete under ordinary SW and BV, uniformly in all printed data, with strict endpoints and finite
errors discharged.",

      "scope": "Completed Section 3 identities are reusable; this full statement is not counted as
partial merely because it cites them. At1162: The actual inclusive R-smooth arithmetic series is
absolutely summable, equals the source finite Euler product and admits an exact finite cutoff/tail
split. At1163: The genuine Euclidean source integrals have proved quadratic and linear frequency decay,
with explicit constants and all cutoffs retained. At1164: Unconditional reciprocal-totient harmonic
estimates, including arbitrary divisor progressions, and the exact gcd divisor expansion are proved.
At1165: The full source arithmetic-family harmonic estimate is proved unconditionally with explicit
divisor exponent2 and constant9 exp(2). At1166: Exact arbitrary-multiplier coefficient identities and
the uniform odd-prime bound8 gcd(p,k*ell)/p are proved. At1168: The genuine coefficient has a uniform
prime-power gcd bound, with every two-adic exponent handled explicitly. At1169: General-modulus source
coefficient decay tau(q)^9 gcd(q,k*ell)/q and principal Gauss decay tau(q)^3/sqrt(q) are proved
unconditionally. At1170: The actual weighted source arithmetic-family and finite denominator-tail bounds
 are proved; the full source arithmetic and completion lemmas remain open with explicit remaining
clauses. At1171: Normalized finite unit averages are proved invariant under reduction to every divisor
modulus. At1172: Primitive progression exponential cancellation and the coprime norm bound are proved
from actual finite unit sums. At1173: The actual Upsilon coefficient is an exact lcm-unit expectation
and satisfies exact simultaneous frequency/denominator reduction. At1174: The actual Upsilon coefficient
 has the proved sharp gcd/divisor decay tau(q) gcd(q,k*ell)/q. At1175: The full source
arithmetic-coefficient lemma is proved: absolute convergence, the all-prime infinite local Euler series
and its exact source G_R value, all three individual bounds with the common divisor exponent9, and the
complete real-cutoff harmonic family estimate. There are no external inputs for this lemma.",
      "remaining": "None. All clauses are proved under the source hypotheses; no extra external
mathematical input.",
      "external_inputs": []

Prime Squares

Initial Formalization Blueprint

and a checked finite core

For Hamed Mousavi
On Equidistribution of Prime Squares and Its Applications

20 October 2026

What has been done. This package contains a first dependency blueprint for the attached 96-page manuscript and a small Lean project. The project formalizes finite exceptional-set inequalities, elementary arithmetic used in the paper, and positivity of the elementary bracket in the last sieve comparison. These are useful components of a larger development; none is a formalization of a headline theorem of the paper.

What this document does not claim. It is not an expanded proof of every lemma, and it is not a certificate for the whole paper. In particular, the circle-method approximation, high–low estimates, stopping-time proof, Ionescu–Wainger argument, ergodic divergence argument and sieve estimates remain to be encoded and checked. The word *target* below always denotes unfinished work.

Source lock. Numbering and page references refer only to the uploaded file `Prime_Squares(32)(1).pdf`. Its SHA-256 is recorded in `PROVENANCE.json`. A revised manuscript must be compared with this snapshot before the paper-to-Lean map is reused.

Reproducibility. Lean is pinned to 4.34.1. Mathlib is pinned to commit `d13f23b723b8a846827a245b89c10fc7d3f11612`. The source archive includes a lockfile, the Lean modules, build instructions and scripts for checking proof dependencies. The verification logs, rather than this prose, record what was actually run.

Reading route. Sections 1–3 define the scope and targets. Sections 4–5 give complete mathematical explanations of the checked components. Sections 6–11 map the unfinished arguments. Sections 12–14 record imports, audit points and the next inputs needed. The appendix inventories numbered statements in the attached PDF.

A Inventory of numbered statements 18

1 The trust boundary

There are three different objects in a formalization project.

1. A **blueprint** specifies mathematical objects, statements, dependencies and proof steps. It is written for humans and can itself contain mistakes.
2. A **Lean proof** is an actual term accepted by Lean's kernel. Elaborating a statement containing a placeholder is not the same as proving it.
3. A **conditional formalization** proves a result from explicitly declared external statements. Its mathematical scope depends on the accuracy and consistency of those statements as well as on the translation of the final theorem.

For the present starter, no extra analytic-number-theory axioms are declared. Theorems in the starter have explicit hypotheses for the errors and main terms they use. Those hypotheses are not assertions that the required analytic estimates have already been established for prime squares.

For the completed project it is reasonable to import deep published results. Each import should have one stable declaration, a precise source, the full range of parameters, and a statement of constant dependence. The project should continue to prove the new arguments of this paper. Assuming its own high–low estimate or its final sieve comparison would leave that part of the paper unverified.

An axiom audit must examine the *transitive* dependencies of each headline theorem, not just count explicit occurrences of `axiom`. Standard Lean/Mathlib dependencies can include `propext`, `Classical.choice` and `Quot.sound`. An unfinished proof introduces `sorryAx`. The starter's scripts reject unapproved dependencies and scan the project sources for proof placeholders and new axioms.

What the Hua example establishes

The supplied Hua blueprint contains both a current-paper development and substantial material from an earlier, broader draft. Its total length is therefore not a useful measure of how long the prime-squares blueprint should be.

At the repository snapshot inspected for this request, the trusted external declarations are `Hua.siegel_walfisz` and `Hua.hua_theorem10`. The second is an exponential-sum estimate, rather than the statement that sufficiently large admissible integers are sums of five prime squares. A static scan of its default library closure passed. That scan does not replace an independent rebuild or an audit of the meanings of its axioms and headline statements. This starter does not import that repository.

2 Objects and final statements to encode

Status: Specifications only; the headline statements are not yet Lean declarations.

Use natural numbers for prime parameters and integer indices for discrete functions. Define, for $N \geq 2$,

$$A_{N,\Lambda} f(x) = \frac{1}{N} \sum_{1 \leq n \leq N} \Lambda(n) f(x - n^2), \quad A_{N,\square} f(x) = \frac{1}{N} \sum_{1 \leq n \leq N} f(x - n^2),$$

$$A_{N,\mathbb{P}^2} f(x) = \frac{1}{\pi(N)} \sum_{p \leq N} f(x - p^2).$$

The first and third operators differ in both weights and normalization. In the divergence theorem the parameter counts the first N primes instead of bounding their size. These conventions must not be silently identified.

Put $L(t) = 2 + |\log t|$, $L_2(t) = 2 + \log(2 + |\log t|)$, and

$$\Phi_c(t) = \exp\left(c \frac{L(t)^{1/2}}{L_2(t)}\right) \quad (t > 0).$$

In bilinear forms define $t^{2/3}\Phi_c(t)$ to be zero at $t = 0$. For $t \geq 0$, define

$$\Psi_C(t) = \int_0^t \exp\left(C \sqrt{\log(e + u) \log(e + \log(e + u))}\right) du.$$

The square root in this last expression covers the *product* of the logarithms.

Theorem 1.1. For every $\varepsilon > 0$, there is C_ε such that the displayed restricted improving inequality holds for every allowed N, F, G with coefficient $4\sqrt{3}/9 + \varepsilon$. The $o(1)$ in the paper is thus a quantifier over ε, not an unspecified function added to the theorem. Strong improving bounds for $3/2 < p \leq 2$ are separate corollaries.

Theorem 1.3. Encode the endpoint sparse form and then the stated interior triangle of exponents. Sparsity uses subsets $E_I \subset I$ of cardinality at least $|I|/10$, pairwise disjoint over the family. Cardinalities, dilations and normalizations must be explicit.

Theorem 1.5. Quantify over every nonatomic ergodic measure-preserving system and every infinite set of indices S. The conclusion is existence of an integrable function whose averages along $N \in S$ fail to converge on a set of positive measure. Do not weaken this to one system or to the full sequence only.

Theorem 1.6. Define $\mathcal{P}$ as the primes represented by $a^2 + b^2 + 1$ with $(a, b) = 1$. For every $A > 0$, specify constants C_A, X_A so that the nonrepresentable $1 \leq n < X$, $n \equiv 12 \pmod{24}$, have cardinality at most $C_A X (\log X)^{-A}$ for $X \geq X_A$.

Section 7. Theorem 7.2 and Corollaries 7.6 and 7.42 are additional targets: the modular estimate, quantitative L^p growth, and almost-everywhere and L^1 convergence on the stated Orlicz class. They are not substitutes for Theorem 1.5.

3 The dependency architecture

Status: Initial map, not a claim that the indicated modules exist already.

Branch	Principal nodes in the paper	Output and main dependencies
Arithmetic	Section 3, especially 3.1, 3.12, 3.14, 3.20, 3.21, 3.24, 3.27	Cohen correlations, kernel bounds, Gauss sums and exceptional-conductor bounds.
Improving	4.1, 4.15, 4.19	Theorem 1.1; uses Section 3 and the decomposition in Section 6.
Sparse	5.1, 5.10, 5.17	Theorem 1.3; needs the local low estimate and maximal, rather than fixed-scale, high estimate.
High–low	6.5, 6.9, 6.14, 6.16, 6.19, 6.21	Proposition 4.19; uses primes in progressions with an exceptional term, minor-arc cancellation and multifrequency estimates.
Near L^1	7.8, 7.15, 7.21, 7.28, 7.2	Corollaries 7.6 and 7.42; uses quantitative Ionescu–Wainger/sampling inputs and the Section 6 model.
Divergence	8.1, 8.6, 8.8 and the final assembly	Theorem 1.5; uses a character-sum bound, Poisson spacings, fixed-modulus prime equidistribution and the divergence criterion.
Goldbach	9.2–9.10, Section 10, 11.13, 11.19, 9.17, 9.20, 9.22, 9.24	Theorem 1.6; circle-method mean-square approximation, two-stage sieving, positive main term and exceptional-set assembly.

The high–low branch is shared by the improving, sparse and near-L^1 results. The divergence branch shares arithmetic foundations but is logically separate from the maximal inequality. The Goldbach branch shares exponential sums and local correlations, but introduces its own mean-square approximation and sieve machinery.

Proposed eventual organization

Keep declarations under `PrimeSquares`. Suggested future directories are `Arithmetic`, `HighLow`, `Improving`, `Sparse`, `Maximal`, `Ergodic`, `Goldbach` and `External`. Maintain one table linking a manuscript label to each Lean declaration. Use stable LaTeX labels once the sources are available; printed theorem numbers alone will change during proofreading.

For each node record: the exact statement; normalization and parameter ranges; dependencies; an expanded proof; Lean name; external assumptions; build status. The appendix currently gives an inventory, not this complete node-by-node expansion.

4 A checked finite exceptional-set argument

Status: Implemented in `PrimeSquares/FiniteAssembly.lean`.

Let S be a finite set, let $e_1, e_2 : S \to \mathbb{R}$, and let $t > 0$. Define

$$B_t = \{n \in S : |e_1(n)| + |e_2(n)| > t\}.$$

No number-theoretic interpretation is part of these definitions.

Lemma 4.1 (Finite energy estimate)**.** *If $\sum_{n\in S} e_i(n)^2 \le B_i$ for $i = 1, 2$, then*

$$|B_t| \le \frac{2(B_1 + B_2)}{t^2}.$$

Proof. For real a, b, the nonnegativity of $(|a| - |b|)^2$ implies $(|a| + |b|)^2 \le 2(a^2 + b^2)$. On B_t, therefore, $t^2 \le 2(e_1(n)^2 + e_2(n)^2)$. Sum this inequality on B_t, enlarge the nonnegative square sum to S, and divide by $t^2 > 0$. □

Lemma 4.2 (Positivity outside the exceptional set)**.** *Let $R(n)$ be a nonnegative integer and suppose that*

$$R(n) \ge M(n) + e_1(n) - e_2(n) - u(n), \quad M(n) \ge 4t, \quad u(n) \le t.$$

If $n \notin B_t$, then $R(n) \ge 2t > 0$.

Proof. Use $e_1 - e_2 \ge -|e_1| - |e_2|$ and $|e_1| + |e_2| \le t$. The lower bound becomes $4t - t - t = 2t$. □

Combining the two lemmas gives the actual Lean result `PrimeSquares.zero_count_card_bound`:

$$|\{n \in S : R(n) = 0\}| \le \frac{2(B_1 + B_2)}{t^2}.$$

The hypotheses about M, R, u, e_i are part of its statement. In the paper's final assembly take $M = \Delta X_n \Theta_n(z)/2$, $t = cN(\log N)^{-C_{A_0}}$, and $e_i = E_i$. If each mean square is at most $C_i N^4 (\log N)^{-K}$, the bound becomes

$$|\{R = 0\}| \le \frac{2(C_1 + C_2)}{c^2} N^2 (\log N)^{-K+2C_{A_0}}.$$

Choosing K large enough yields the desired logarithmic saving for this finite range. The analytic estimates, eventual parameter choices, identification of R with actual representations, and treatment of the initial short range remain formalization work. Thus this is the finite last step of the Goldbach proof, not Theorem 1.6 itself.

5 Other checked components

Status: Implemented in `LocalArithmetic.lean` and `SieveConstant.lean`.

Congruences and the shared-prime observation

For every natural number n with $n \equiv 1 \pmod 2$ and $n \not\equiv 0 \pmod 3$, the module proves $n^2 \equiv 1 \pmod{24}$. The proof reduces to the 24 possible residues; Lean checks the finite case split. For a prime $p > 3$, primality excludes divisibility by 2 and 3, so the same conclusion follows.

Consequently, if $r \equiv 11 \pmod{24}$ and $p > 3$ is prime, then $r + p^2 \equiv 12 \pmod{24}$. The restriction $p > 3$ is included explicitly. The starter also proves the shift equivalences

$$m = a^2 + b^2 + p^2 \iff m + 1 = a^2 + b^2 + p^2 + 1, \qquad m \equiv 11 \pmod{24} \iff m + 1 \equiv 12 \pmod{24}.$$

These clarify the relation between the abstract's formulation and Theorem 1.6; they do not establish an exceptional-set estimate.

Suppose p, m are prime, $n = m^2 + r$, and $p \mid n, r$. Then $p \mid m^2$, so $p \mid m$; primality of m forces $p = m$. This is the finite divisibility observation used in Lemma 11.2. The divisor-counting estimate and the full sieve comparison in that lemma are not yet formalized.

The elementary bracket in Lemma 9.24

The manuscript reduces its final sieve comparison to

$$\Delta \geq \frac{e^{\gamma/2}}{\sqrt{\pi}} \left(\frac{2\sqrt{2}}{3} \log 2 - \frac{27}{64} \right).$$

Lean proves positivity of the parenthesized expression. There is a particularly short rigorous proof which does not need decimal approximations:

$$\sqrt{2} \geq \frac{4}{3}, \qquad \log 2 \geq 1 - \frac{1}{2} = \frac{1}{2},$$

where the second inequality is the standard $1 - x^{-1} \leq \log x$ for $x > 0$. Both lower bounds are positive, and therefore

$$\frac{2\sqrt{2}}{3} \log 2 - \frac{27}{64} \geq \frac{4}{9} - \frac{27}{64} = \frac{13}{576} > 0.$$

The declaration `sieve_bracket_positive` proves this conclusion. The separate declaration `scaled_sieve_bracket_positive` allows multiplication by any strictly positive real factor.

This does *not* verify the integral evaluation for $f_{1/2}(9/8)$, the upper bound on $\mathcal{W}(9/8)$, the factor $e^{\gamma/2}/\sqrt{\pi}$, or the stronger numerical inequality $\Delta > 0.17$. Those must be added before claiming Lemma 9.24.

6 Improving estimates: the scalar optimization and its inputs

Status: Unfinished target; the following is the blueprint for Section 4.

Separate the prime parameter from the spatial scale. For prime squares, a sum up to N has support at scale N^2; the abstract theorem uses a spatial-scale variable. A typed name such as `primeScale` versus `spaceScale` prevents an incorrect substitution of N for N^2.

Theorem 4.1 first supplies a comparison operator B_N. Applied to indicators, its decomposition gives, with $\delta = |F||G|/N^2$,

$$N^{-1}|\langle B_N \mathbf{1}_F, \mathbf{1}_G\rangle| \lesssim \delta J^s (\log J)^\gamma + \delta^{1/2} J^{-r} (\log J)^\beta.$$

The optimal J, up to bounded factors, is

$$J = \delta^{-1/(2(s+r))} (\operatorname{Log} \delta)^{(\beta-\gamma)/(s+r)}.$$

Prove first the estimate when this J is in the permitted range. If it is too large, use the elementary local kernel estimate. This second branch is essential: choosing an inadmissible J is not an application of the decomposition.

For the prime operator the corresponding bound is

$$\delta Q^s (\log Q)^\alpha + \delta^{1/2} Q^{-r} \exp\left(c_1 \frac{(\log Q)^\kappa}{\log\log Q} \right) + \text{error}.$$

When $\operatorname{Log}\delta$ is small enough relative to $(\log N)^c$, take the dyadic Q specified by (4.14). Prove separately that it is admissible, that rounding changes the estimate by a bounded factor, and that the error is absorbed. In the complementary range, transfer the comparison estimate using the pointwise domination by B_N. This yields

$$\delta^{1-s/(2(s+r))} \Phi_{c_*,\kappa}(\delta), \qquad c_* = \frac{c_1 s}{2^\kappa (s+r)^{\kappa+1}} + o(1).$$

For $s = 1, r = 1/2, \kappa = 1/2, c_1 = 2 + \varepsilon$, the critical power is $2/3$ and the limiting coefficient is $4\sqrt{3}/9$.

Separate Lean tasks. Establish the finite bilinear norm inequalities; formalize the elementary optimization including the two parameter ranges; prove the dyadic-to-full annular summation; and then prove restricted-to-strong interpolation for $p > 3/2$. None follows just from writing the numerical value of the coefficient into a declaration.

7 Sparse bounds: local control and recursion

Status: Unfinished target; Sections 5 and the stopping-time conventions in Section 2.

The sparse proof needs more than Theorem 1.1. A stopping time $\tau(x)$ depends on the spatial point. Its high term must be controlled by a maximal ℓ^2 estimate over all permitted scales. The low estimate must be local enough that admissibility replaces its local density by the parent density.

The key tasks are these.

1. Define integer intervals, their dilations, a dyadic grid, and the admissible stopping times. Record the exact support radius of each kernel.
2. Prove Lemma 5.1 from the local kernel estimate, the local low estimate, the maximal high estimate and the square-summable errors. Include the small-scale branch, where the abstract high–low split is not available.
3. Prove Lemma 5.10. Select maximal bad dyadic intervals by the two density tests. Bound the sum of child lengths by $|I_0|/4$. Construct disjoint major subsets and iterate the local inequality.
4. In Lemma 5.17 split according to $\log \tau \le C_0 L^2$ and its complement, where $L = \mathrm{Log}(\delta_0^{-1})$. The first range uses the square averages; the second uses the prime-square decomposition with an admissible denominator cutoff.
5. Convert the local sparse form with cI on the input side into the stated form. Prove the required grid/dilation reduction rather than identifying the two families by notation.

For finite input sets, begin with a finite set of scales and a finite recursion. If using an infinite family later, specify its sum and prove the limiting step. This keeps the initial recursive construction elementary and exposes precisely which part needs an infinite argument.

There is a useful formalization trap here. An arbitrary real-valued supremum in Lean uses conditional completeness. Without a boundedness hypothesis, it must not be treated as a maximum with all the usual inequalities. One can first work with finite truncated maxima, or use extended nonnegative reals for a maximal function and prove finiteness afterward.

Finally, the strong sparse estimates for exponents in the interior of the triangle need their own interpolation/convexity argument. They should be separate declarations depending on the endpoint local bound and the trivial bounds, not an additional assumed theorem.

8 The high–low model and exceptional conductors

Status: Unfinished target; the main shared arithmetic and analytic branch.

At prime scale N, the annular multiplier is approximated by the model V_N in (6.8). Its ordinary coefficients are normalized unit quadratic Gauss sums. If an exceptional character is present, its contribution has the minus sign displayed in that formula, an induced character modulo each multiple of its conductor, and a continuous model with parameter β.

Use explicit scale-indexed data. For example, define an optional datum at N containing (q_χ, χ, β), and define $\mathcal{M}(\chi)$ to be the scales where that character is selected. Do not pick one character and use it at all scales. Page uniqueness must be strong enough to justify the later regrouping by conductor.

Arithmetic layer. Prove the Cohen correlation by CRT, the odd prime-power evaluation and the explicit 2-adic cases. Build the restricted correlations and Euler products of Section 3 from these identities. Prove the ordinary Gauss bound with its subexponential factor, the real-character bound, and the stronger $\sigma_\chi B_\chi^{1/2} \ll q_\chi^{-1/25}$ estimate. The last estimate is used to sum over changing exceptional characters.

Approximation layer. Encode Lemma 6.5 and then Lemma 6.9. The primes-in- progressions input must supply a single exceptional datum valid over the interval of partial summation $[N/2, N]$, with uniform errors. A fixed-modulus PNT alone does not provide this growing-modulus input.

Exact decomposition. The ordinary split is by $q \le Q$. The exceptional split is by $d = q/q_\chi \le Q/B_\chi$, with its own cutoff. Prove the multiplier identity (6.13) before norm estimates. Empty exceptional sums, including $Q/B_\chi < 1$, must be covered by the definitions.

Low and high bounds. Proposition 6.14 uses inverse transforms and the arithmetic kernel identities. Proposition 6.21 needs Lemma 6.16, the denominator- prefix extension 6.19, the cutoff-difference square functions, and a final sum over χ. At each scale there is at most one exceptional datum; the square sum over characters and Page uniqueness per dyadic conductor range are separate steps. Only after both bounds and the error estimate are checked does one obtain Proposition 4.19.

9 The Orlicz maximal estimate and convergence

Status: Unfinished target; Section 7.

The quantitative Ionescu–Wainger input must retain its constants. Proposition 7.8 specifies a rational-frequency set containing every denominator at most Q, a period P, a denominator bound B, a sufficiently small width, and norm comparisons for a range of exponents. It invokes Tao's Lemma 5.1, Theorems 1.6 and 1.7, and Proposition 1.5. These should have explicit external interfaces if they are not formalized here.

Next prove the continuous multiplier bounds uniformly in $0 < \beta \leq 1$ (Lemma 7.15), followed by the finite-group measure and sampling argument (Proposition 7.21). The measure is allowed to be complex but has total variation at most one. Dependence of constants on the period or on β would break the later optimization.

Proposition 7.28 combines this low model with an ℓ^2 high estimate. The exceptional characters of conductor above Q vary with scale and are retained in the high term. The low exceptional character, when it exists, is controlled using Page uniqueness. This assembly must use the same model and normalization as Section 6.

For the modular extension, do not stop at the restricted estimate on $\mathbf{1}_F$. Let C_∞ bound the masses of the positive kernels. Remove $|f| \leq \lambda/(2C_\infty)$. Decompose the remaining function into level sets

$$E_j = \{2^j\lambda/(2C_\infty) < |f| \leq 2^{j+1}\lambda/(2C_\infty)\}.$$

Allocate thresholds using a positive summable sequence such as $a_j = 6/(\pi^2(j+1)^2)$. Prove the union inclusion, apply the restricted estimate to each E_j, and prove that the polynomial factor in j inside the threshold can be absorbed by enlarging the coefficient of Ψ_C. This is a quantitative estimate for this particular Young function, not just sublinearity. It gives the truncated modular estimate (7.3), then (7.4).

Corollary 7.6 follows by layer cake and a one-variable integral estimate, with $\varepsilon = p - 1$. Corollary 7.42 first transfers finite truncated discrete estimates to an invertible probability-preserving system. Prove bounded-function convergence using the cited polynomial-prime result and control the higher prime powers there. Abel summation handles the unweighted prime averages. Finally use Orlicz truncation, doubling and the modular maximal estimate to pass to unbounded functions; use uniform L^1 bounds for L^1 convergence.

10 Persistent universal divergence

Status: Unfinished target; Section 8.

For each modulus q, define $\Lambda_q = \{b^2 \bmod q : (b,q) = 1\}$. The initial finite tasks are CRT compatibility, inclusion in the prime-square residue set, and, for odd squarefree q,

$$|\Lambda_q| = \frac{\varphi(q)}{2^{\omega(q)}}, \qquad s_q = \frac{q}{|\Lambda_q|} = \prod_{p \mid q} \frac{2p}{p-1}.$$

The inclusion uses Dirichlet's theorem for a unit square root; it must not claim that every prime residue, including nonunits, is part of Λ_q.

Lemma 8.8 expands each quadratic-residue indicator as $\frac{1}{2}(1 + \chi_p - \mathbf{1}_{\{0\}})$. Terms containing a zero indicator are bounded by a constant depending on the number of shifts. For the others, apply the Weil bound to the squarefree product of the distinct shifted linear factors. This proves the correlation hypothesis for the imported Poisson-spacings theorem.

Choose pairwise disjoint blocks of odd primes with block sizes tending to infinity, and a disjoint prime sequence u_j. The block products q_j satisfy $\mathbb{P}_{q_j}(\Lambda_{q_j}) \le 2^{-j}$, whereas $\mathbb{P}_{u_j}(\Lambda_{u_j}) \ge 1/3$. The construction must ensure the combined collection is pairwise coprime.

Theorem 8.6 supplies Poisson spacings. The thickening identity in the proof expresses the covered proportion as

$$\mathbb{P}_{q_j}(\Lambda_{q_j}^{\gamma}) = \int_0^{\gamma} F_j(\theta)\, d\theta + O(s_{q_j}^{-1}).$$

Dominated convergence gives $1 - e^{-\gamma}$, so the deficit is $o(\gamma)$. The pair-separation condition uses LaVictoire's Lemma 3.2 in addition to this one-gap distribution; it is not an automatic restatement of Poisson convergence.

Finally, fixed-modulus prime equidistribution gives limiting mass $1/|\Lambda_Q|$ at every $a \in \Lambda_Q$. The strict lower bound required by (8.5) then holds with, for example, $\beta = 1/2$. Apply the full imported divergence criterion, including its transference/Banach-principle conclusions, to obtain exactly the persistence and system quantifiers of Theorem 1.5.

If the chosen formal ergodic infrastructure assumes invertibility, a separate extension/transfer argument is needed to match the unqualified system statement in Theorem 1.5. Simply adding invertibility would narrow the theorem.

11 The Goldbach branch

Status: Only the finite final assembly and small supporting pieces are checked.

The reductions in Section 9 produce a lower sieve count minus an upper correction count. Their errors must have mean-square bounds with an arbitrarily large logarithmic saving. The common main term is $X_n\Theta_n(z)$; its positivity and uniform lower bound are separate lemmas.

Circle method. Lemma 9.10 is the principal target. Its coefficients are independent of n, and its conclusion is a mean square of a sum over auxiliary moduli and ℓ. Section 10 supplies the minor-arc bound, the major-arc local factor G_R, the truncated continuous factor $H_{\ell,R}$, the tail estimate and the major-arc error. The same small-prime parameter R must be retained in both main-term factors until its tails have been shown to be summable.

Sieve. Lemma 11.2 replaces variable sets of sieve primes by fixed sets, which is needed before applying Lemma 9.10 to coefficients independent of n. The exact local densities are computed in Lemmas 11.6 and 11.8. For primes at most R, the uniform product dimensions are $2/3$ and $3/2$; one cannot apply the desired half-dimensional and linear sieves over the whole range.

Lemma 11.13 removes $p \le R$ first at level $D_0 = \exp((\log\log N)^3)$. The remaining level is D/D_0. Because outer weights have both signs, the choice of preliminary upper or lower weights must depend on that sign. Prove this finite algebra before estimating the two stages. The coefficient bounds and independence of n must survive the combination. The outer dimensions are then $1/2$ and 1.

Lemma 11.19 performs the weighted sum over ℓ. It needs the cited mean-value theorem for multiplicative functions and the relevant short-interval uniformity. Track the cancellation of the factors at $p \le R$ and the replacement of $H_{\ell,R}$ by H_ℓ; neither can be dropped at the definition stage.

The outputs are Propositions 9.17 and 9.20. Lemma 9.22 bounds the common main term below. Lemma 9.24 compares the sieve constants. Their combination gives (9.25), and the checked finite result in Section 4 then applies. The remaining asymptotic task is to choose the constants in the correct order, show the $O(N^\varepsilon)$ nuisance is smaller than the positive main term, discard the initial range, and pass from scale N^2 to general X.

12 Proposed external-input register

Status: Candidate interfaces; not declarations already installed in the starter.

The user's permission to leave deep theorems unformalized makes a conditional development appropriate. The exact declarations should be approved mathematically by comparison with their sources. The list below is an initial register, not a claim that each result is absent from current Mathlib.

ID	Published input	Required interface and use
NT01	PNT in progressions with exceptional term and Landau–Page; paper (2.5)–(2.6), reference [22]	Uniform growing-modulus error, one datum on an annulus, induced characters, and uniqueness strong enough across scales. Used in Section 6.
NT02	Siegel–Walfisz and fixed-modulus equidistribution	Full quantifier order for modulus, residue, exponent and threshold. Used where polylogarithmic moduli or fixed progressions suffice; not a replacement for NT01.
NT03	Ren [40, Theorem 1]	Quadratic prime exponential-sum cancellation with exactly the denominator and arc-width ranges needed in (6.7) and (10.1).
NT04	Bombieri–Vinogradov, Brun–Titchmarsh, Mertens-type estimates; Section 2.6	Maxima over residues and endpoints, divisor weights, and constants uniform in the auxiliary moduli. Used in Section 10 and the sieve.
NT05	Classical quadratic Gauss evaluations and Weil character-sum bounds	Primitive and induced character conventions; primes and prime powers, including 2; squarefree-polynomial hypothesis for Lemma 8.8.
HA01	Separated-frequency maximal inequality [25, Theorem 1.1]	Precise separation and cardinality dependence. Prove its adaptation, transference and uniformity in β in Lemma 6.16.
HA02	Tao [45], Lemma 5.1, Theorems 1.6–1.7 and Proposition 1.5	Quantitative major-arc construction, multiplier theorem and sampling comparisons. Keep $r, k, B, P, \varepsilon, p$ and vector-valued constants explicit.
HA03	Hardy–Littlewood, Calderón–Zygmund, Khintchine and Rademacher–Menshov	Only use an external declaration where the pinned library does not already provide the needed statement. Preserve the $p \downarrow 1$ dependence.

Do not collapse these into a single assumption saying that all estimates needed in the paper hold. An import should be independently recognizable as a published theorem and should not assume the novel conclusion to be checked.

External inputs continued

ID	Published input	Required interface and use
ER01	LaVictoire [27, Theorem 3.1 and Lemma 3.2], with the principles used in the paper's Theorem 8.1	CRT families, two coprime sequences, thickening deficit, pair separation and residue-frequency hypotheses; full persistent universal divergence conclusion.
ER02	Granville–Kurlberg [14, Theorem 1], in the specialization 8.6	Uniform correlations for distinct shifts and the hypotheses on local densities; convergence of normalized cyclic gaps.
ER03	Polynomial-prime pointwise convergence [35, Corollary 2(ii)]	The bounded-function dense class used in Corollary 7.42, with the correct weights and systems. Prime powers and Abel summation remain internal tasks.
SV01	Rosser–Iwaniec coefficient-form sieve and fundamental lemma [21]	Weights, support, signs, coefficient bounds, product hypotheses, sieve functions and quantitative remainder; prove the two-stage composition in Lemma 11.13.
SV02	Granville–Koukoulopoulos [13] and Shiu [41]	Mean values of the particular multiplicative weight and uniform estimates in the retained ranges used by Lemma 11.19.

Represent imports as hypotheses first

For a new branch it is often helpful to package the external inputs as a named structure and prove a theorem with that structure as an explicit argument. This makes the logical boundary visible without immediately adding global axioms. Once the interfaces have been audited, a separate file can instantiate the structure from selected quoted theorems.

In either design, dependency output for a headline theorem must agree with the published import register. A proof conditional on an estimate proved nowhere in the project or cited literature should be labeled incomplete, even if Lean accepts it with that estimate as a hypothesis.

Possible reuse from the Hua project

The Hua repository contains finite cyclic Fourier infrastructure, quadratic local arithmetic and analytic assembly. Some may be reusable after comparing definitions. Its prime-square weights are those of its own W-trick argument, not automatically the operators $A_{N,\Lambda}$ in this paper. Reuse requires checking signs, normalizations, finite versus infinite groups, and transitive axiom dependencies. No reuse has been counted as completed work here.

13 Points to settle during manuscript proofreading

These are formalization requirements or visible editorial issues, not a verdict that the main mathematical arguments are wrong.

1. **Freeze the version.** The attached paper has 96 pages and Section 7. Its current numbering is the one used in this document. Match the final LaTeX labels rather than importing numbering from older discussions.
2. **Repair the Section 7 references.** The opening of Section 7 and the last sentence before the proof of Corollary 7.6 refer to Theorem 1.5. In this snapshot Theorem 1.5 is the divergence theorem, so these references cannot name the maximal-inequality consequence intended there.
3. **Preserve the two endpoint functions.** The improving loss is $\exp(c\sqrt{L}/L_2)$; the modular function uses $\exp(C\sqrt{\log(e+t)\log(e+\log(e+t))})$. These are different scales.
4. **Separate bounded and unbounded input.** A negligible prime-power contribution for bounded functions is sufficient for the dense-class convergence step; it is not itself a uniform error bound for every L^1 function.
5. **Make exceptional data consistent.** Record the annular data used in partial summation and prove the regrouping over $\mathcal{M}(\chi)$. Do not replace this by a single exceptional character fixed for all N.
6. **Expose uniformity in the Goldbach range.** All $o(1)$, tail errors and positivity bounds must be uniform in admissible n, ℓ and auxiliary moduli. Write the order of choosing A_0, K, C and all thresholds explicitly.
7. **Retain fixed sieve-prime sets.** The independence from n after Lemma 11.2 is required by the mean-square estimate. The coefficient combination in the pre-sieve must preserve this independence.
8. **Check strictness and small cases.** Empty sets, $q = 1$, powers of 2, $N \geq 2$, $p = 2, 3$, and equality at density/threshold boundaries should be covered by exact definitions, not silently discarded.

The present work has not audited every cited theorem or every proof in the PDF. In particular, successful checks of the starter do not validate any unfinished node elsewhere in the map.

14 What is needed to continue

The PDFs were enough to start. The next useful input is the final LaTeX project: all source files, bibliography, custom macros and any code used for numerical estimates, together with the PDF generated from those files. This makes the statements and labels unambiguous and lets the map track proofreading changes.

GitHub is useful for versioning and automated builds, but an account is not required to write or check Lean locally. This archive is a normal Lean project; it can be uploaded later. The toolchain and lockfile are already selected. There is no need for the author to learn Lean before mathematical work can begin.

The next mathematical milestone should be one coherent branch. A practical sequence is:

1. Encode the final target statements and audit their quantifiers against the LaTeX. Build a stable statement map.
2. Complete a substantial finite arithmetic module, such as the quadratic Cohen identity with all prime-power cases, or complete the scalar optimization in Theorem 4.1.
3. Specify and audit the deep-input interfaces. Prove one full branch from those interfaces, without assuming its novel intermediate estimates.
4. Add the remaining branches and report the exact dependencies of each headline theorem separately.

For the Goldbach branch, the existing checked finite assembly supplies an endpoint to which the circle-method and sieve components can connect. For the harmonic- analysis branch, the shared high–low decomposition is the principal reusable milestone. The divergence branch can be developed separately once its external criterion and Poisson-spacings interfaces are audited.

Completion criterion. A full conditional formalization requires a fresh build of every target theorem, a transitive axiom audit with no unfinished proof axiom, and a human comparison of the final statements and imported inputs with the manuscript and sources. A long blueprint, a clean source scan, or a passing build of the present starter alone does not meet that criterion.

Current deliverable. This is an initial, reproducible starting point with small checked components and an explicit account of the much larger unfinished work. It should not yet be described in an arXiv or journal submission as a formalization of the paper.

A Inventory of numbered statements

The following inventory was extracted from headings in the attached PDF. Planned names are suggestions only. A status of "target" means no proof of that numbered statement is present in the starter. Checked supporting subclaims are described separately in Sections 4–5; they do not change the status of the enclosing paper theorem or lemma.
