The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved. Sparse applications additionally record OrdinarySquareStoppingInput CS and IndependentPrimeMaximalInput as explicit

independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion.

`Checkpoint_845_IWFiniteFrequencyGeometry.md`

Checkpoint 845: Actual finite IW frequency geometry from the independent raw construction

The actual finite IW frequency set is defined using canonical rational representatives and denominators dividing products of at most k positive coprime integers. Its exact membership and denominator bound are proved. A narrow independent construction interface records Tao arXiv:2008.05066v2 Lemma5.1 for arbitrary rho and natural Q: positive coprime components, rational coverage, a common period at most 3^Q and the raw component bound. Its existence remains unproved and it contains no multiplier, sampling or current-paper maximal statement. From that input Lean proves the quantitative frequency geometry, including every denominator<=B and 4 epsilon B^2<1. The full goodness, multiplier and sampling clauses of source p:IWinput7 remain unfinished, so no full source proposition is awarded.

`Checkpoint_847_IWGoodness.md`

Checkpoint 847: Full quantitative Ionescu-Wainger goodness with an integer component maximum

The full Ionescu-Wainger goodness condition in Tao Definition1.3 (c=1/2) is now proved for the actual quantitative parameters. A natural integer maximum component is chosen without rounding the real component bound upwards; this avoids an erroneous factor exponential in r*k. The proof shows qmax^(2*r*k)<=B^(2*r) and the strict epsilon<1/(4*r*qmax^(2*r*k)) inequality, not just pairwise separation. Combined with the existing independent raw Tao construction, Lean now returns an actual finite frequency set with coverage, period, denominator cap and genuine goodness. The general multiplier/sampling and current-paper low/high estimates remain separate work and are not assumed here.

`Checkpoint_848_RealLineFourierMultipliers.md`

Checkpoint 848: Actual real-line Fourier multipliers and Lp norm interfaces

The real-line Fourier multiplier is now an actual continuous linear operator on real-line L2, built from Mathlib's unitary Fourier transform, multiplication by a bounded continuous symbol, and inverse Fourier transform. Lean proves the Fourier identity and symbol-norm operator bounds. General-p real and integer multiplier bounds require both Lp membership and the explicit extended-norm inequality on the L2 intersection; neither bound is assumed merely by declaring its predicate. The newly needed pinned Mathlib Fourier Lp dependency was compiled from the unchanged pinned sources (dependency build log retained). This checkpoint provides the actual operator interface for a general independent IW theorem, but does not yet prove the current paper's quantitative low/high or restricted maximal estimate.

Checkpoint_849_CyclicSquareMeasures.md

Checkpoint 849: Concrete cyclic square measures and exact Fourier coefficients

The finite cyclic low-model measure is now concrete: it is the pushforward of the character-weighted uniform measure on units under u -> u^2, normalized by phi(P). Lean proves its action on every test function, total variation at most one for every complex Dirichlet character, and exact equality of its finite Fourier coefficients with the existing twisted quadratic sums, with the manuscript's minus sign and totient normalization. The principal character gives the existing principal square sums. These identities remove an arithmetic identification premise at the full period; passage to a smaller denominator and conductor cancellation are subsequent work. No quantitative low maximal or prime-square restricted estimate is assumed or claimed.

`Checkpoint_850_UniformFiniteGroupAverages.md`

Checkpoint 850: Uniform finite-group averages and kernel cancellation

Lean now proves two general finite-group identities needed by the arithmetic IW comparison. Pullback under any surjective finite-group homomorphism preserves the normalized complex average; a translation and double-counting argument gives the exact normalization without an unverified equal-fibre assertion. For any complex multiplicative character that is nontrivial on the kernel, every character-weighted pullback test sum is zero. These are proved supporting lemmas, with no external analytic assumptions. They will be applied to reduction of unit groups at divisors of the IW period.

Checkpoint_851_CyclicConductorCoefficients.md

Checkpoint 851: Conductor-sensitive cyclic Fourier coefficient identity

The coefficient identity used in the current-paper IW comparison is now proved at every q dividing the period P. The Fourier coefficient of the actual cyclic square measure descends exactly to the twisted quadratic sum for a character that factors through q, and is zero when its conductor does not divide q. Lean derives the cancellation witness from Mathlib's conductor and kernel criterion and applies the proved finite-group averaging identities. The rational circle Fourier coefficient is also identified with this reduced coefficient, retaining the negative phase; the principal measure reduces to the existing principal square sum. This removes the equal-fibre and character-cancellation assertions from the remaining comparison boundary. No low/high norm conclusion is a hypothesis or a claimed proved source result.

Checkpoint_852_IWMultiplierInterface.md

Checkpoint 852: Actual smooth IW multiplier interface and quantitative specialization

The independent IW multiplier boundary now acts on the actual Fourier operators, rather than unspecified normed objects. Its explicit hypothesis ranges over arbitrary good coprime finite sets, smooth compact real symbols, finite cyclic measures, and the full admissible p interval; the assertion includes actual output Lp membership and the extended-norm inequality. This is an unformalized independent theorem (Tao Theorem1.7, with finite cyclic specialization), not a new axiom and not a claim that Mathlib proves IW. Lean proves its specialization to the manuscript's checked geometry and constants. The actual finite periodized symbol has a proved real-frequency formula, and its cyclic coefficients have the proved variation bound. The smoothness and real Lp estimate for each concrete annular symbol must still be verified before using this interface; the paper's own low/high and restricted estimates are absent from the external hypothesis.

`Checkpoint_853_IWAnnularDenominatorTails.md`

Checkpoint 853: Actual Q-to-minus-one-quarter annular denominator-tail maximum

The denominator tail with the original denominator-dependent cutoff now has an actual countable maximal L2 majorant of size K*Q^(-1/4). Lean proves the power split q^(-3/8)<=Q^(-1/4)*q^(-1/8), applies the previously checked power-decaying annular maximal theorem, and specializes the result to the actual principal and twisted quadratic coefficients using the project's proved Gauss decay. The result allows variable beta and variable upper denominator truncation, and its constant is uniform in Q, the input, and the character family. It uses only the already declared generic smooth multifrequency boundary. This proves the original-cutoff denominator-tail contribution; the common IW-cutoff tail, small-denominator difference, changing-character sum and low-term maximum remain necessary for the full comparison.

`Checkpoint_854_CommonCutoffGeometry.md`

Checkpoint 854: Common-cutoff factorization and contraction on each denominator band

Lean now proves the exact relation between a common narrow cutoff and the original denominator-band cutoff. When the common width lies in the band cutoff's core, the actual periodized annular symbol factors as the original annular symbol times the common cutoff. The proof treats integer periodization explicitly and rules out cross-lift contributions. For a separated denominator band, the sum of common cutoffs defines an actual integer Fourier multiplier of operator norm at most one. This is the projection needed for the IW-cutoff high tail; it is proved, rather than included in an external sampling or maximal premise.

`Checkpoint_855_CommonCutoffAnnularMaximum.md`

Checkpoint 855: Actual common-cutoff annular maximum on a denominator band

The common-cutoff annular block on a denominator band is now exactly the original annular block composed with a fixed Fourier projection. Lean proves that cross-frequency products vanish, the symbol factorization, and the resulting actual countable dyadic L2 maximum, uniformly in the common width and variable beta. The projection is applied separately on each band, avoiding unjustified cross terms from a single projection over all denominators. The only analytic hypothesis is the previously recorded general smooth multifrequency estimate.

The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved. Sparse applications additionally record OrdinarySquareStoppingInput CS and IndependentPrimeMaximalInput as explicit independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion. Section7 additionally records the independent RawTaoArcConstructionInput C, used only to obtain actual finite IW frequency geometry. Its existence is unproved; multiplier, sampling, low and high norm estimates are not fields and remain unfinished.

`Checkpoint_856_CommonCutoffPowerMaximum.md`

Checkpoint 856: Summed common-cutoff maximum and Q-to-minus-one-quarter tail

The separate denominator-band projections are now summed in Lean. The actual common-cutoff annular maximum is bounded uniformly by a convergent polynomial-geometric series for every positive coefficient decay exponent. Splitting q^(-3/8) then gives the required Q^(-1/4) bound for the common-cutoff denominator tail, for any finite canonical frequency set whose common width lies in the relevant band cores. The proof includes empty bands, the finite dyadic partition and the infinite scalar sum. The exact IW parameters and arithmetic cyclic coefficients will now be substituted into this checked estimate.

frequency geometry. Its existence is unproved; multiplier, sampling, low and high norm estimates are not fields and remain unfinished.

`Checkpoint_857_CyclicRationalGaussDecay.md`

Checkpoint 857: Uniform Gauss decay of actual rational cyclic coefficients

The actual rational cyclic coefficients now inherit the project's proved uniform Gauss decay for every exponent below one half. Lean first identifies the rational circle coefficient with reduction at its exact reduced denominator, then proves the principal and induced-character identities and the nondividing-conductor zero case. The uniform bound is independent of the period and the character. This supplies the real coefficients needed to specialize the common-cutoff tail, without an assumed arithmetic coefficient bound.

`Checkpoint_858_IWCommonCutoffTails.md`

Checkpoint 858: Actual quantitative IW common-cutoff denominator-tail maximum

The common-cutoff tail is now specialized to the exact quantitative IW parameters and the actual cyclic square measures. Lean proves that epsilon^(-1) lies inside every needed denominator-band core, then combines the actual frequency geometry and the proved uniform cyclic Gauss decay to obtain a countable dyadic L2 majorant of size K*Q^(-1/4). The constant is uniform in r,k,Q, period, complex character and variable beta. This proves the common-cutoff denominator-tail contribution for both the principal and any

fixed induced character. It does not require the external IW multiplier theorem or assume the low-model maximum; only the previously declared generic smooth multifrequency input is used.

`Checkpoint_859_IWSmallDenominatorDifference.md`

Checkpoint 859: Actual small-denominator cutoff-difference maximum

The remaining small-denominator cutoff difference now has a proved actual countable maximal L2 bound. The proof compares the two real cutoffs on their common core, uses the already proved annular Fourier decay outside that core, and passes through the actual circle periodization and integer Fourier operator. For a finite frequency set Gamma the bound is 24*card(Gamma)*A*epsilon^(-1)/(pi*M^2), uniformly in variable beta. This is a deliberately coarse finite-count bound, valid without separation, whose polynomial denominator cost can be absorbed by the manuscript's sufficiently large starting scale. The absorption into Q^(-1) and the final comparison assembly are still separate proof obligations.

`Checkpoint_860_IWLargeConductorMaximum.md`

Checkpoint 860: Actual Q-to-minus-one-quarter changing large-conductor maximum

The changing large-conductor exceptional contribution now has an actual countable maximal L2 majorant of size K*Q^(-1/4). Lean keeps the original rational annular symbols, permits the exceptional character to vary with scale, and proves uniformity by splitting the Gauss decay between Q, the conductor and the remaining denominator. The already checked Page uniqueness theorem bounds the sum over conductor classes. No fixed-character substitution and no current-paper exceptional maximal estimate is assumed. The only hypotheses are the independently recorded smooth multifrequency and raw Page uniqueness inputs.

`Checkpoint_861_IWFixedSmallCharacter.md`

Checkpoint 861: Actual fixed small-character selection and IW period divisibility

Lean now constructs the fixed small-conductor Page datum used by the low model. It proves uniqueness across all scales in the fixed conductor region directly from the existing raw Page theorem, retaining the original scale-by-scale activity and allowing inactivity. It also proves that every small denominator q>=2 divides the actual IW period, using coverage of the rational point 1/q; hence the selected small character can actually be induced to that period. Neither the existence of a fixed character nor its period divisibility is left as a current-paper external premise.

not fields and remain unfinished.

Checkpoint_862_IWActualAnnularSymbols.md

Checkpoint 862: Actual annular IW symbols and primitive-character identification

The actual annular low symbol is now connected to the real-line/IW operator interface, with a proved bounded continuous real symbol and exact equality to the finite periodized circle symbol. Lean also identifies a primitive character induced to the IW period with its original masked quadratic coefficients at every IW rational frequency. The principal and induced-character whole-sum identities are proved, including the conductor-not-dividing zero case. This supplies a concrete low operator for the comparison; no general-p continuous or low maximal bound is claimed by this identification.

`Checkpoint_864_IWQuantitativeModelComparison.md`

Checkpoint 864: Quantitative actual original-versus-IW maximal L2 model comparison

The exact comparison and all three associated maximal estimates are now assembled in Lean into a genuine countable L2 model comparison with Q^(-1/4) rate. It compares the original denominator-dependent circle multiplier with the common-cutoff IW multiplier on the same dyadic scales and variable beta. The small-denominator contribution is absorbed under the explicit arithmetic starting budget (Q+1)^2*epsilon^(-1)*Q<=M^2. The coefficient decay and small coefficient bound are internal premises for this generic comparison, to be discharged by the actual principal/character coefficients; they are not added as independent analytic inputs. The source's large starting-scale formula must also be shown to imply that budget before the full source proposition is closed.

Its existence is unproved; multiplier, sampling, low and high norm estimates are not fields and remain unfinished.

`Checkpoint_866_IWStartingScaleBudget.md`

Checkpoint 866: Starting-scale budget proved from the manuscript exponential scale

The starting-scale budget in the quantitative model comparison is now proved from the manuscript's exponential scale, with an explicit constant 25. For C_*>=e, Lean proves log B>=1, log(epsilon^(-1))<=17*r*log B, and (Q+1)^2*epsilon^(-1)*Q<=exp(25*((log Q)^2+r*log B)). Consequently any integer M>=2 above this exponential threshold satisfies the squared-size budget needed to absorb the small-denominator cutoff difference. Thus the coarse finite-count estimate does fit the source's permitted sufficiently large absolute constant; no extra growth condition is being silently imposed.

Checkpoint notes 867-941

Checkpoint_867_IWOptionalModelIdentities.md

Checkpoint 867: Exact optional Page model and actual IW low-symbol identities

The fixed-small/large-character split and the complete optional circle-model comparison are now exact identities of actual symbols. The low operator retains the original activity at each scale, and its fixed character term is identified with the actual cyclic square measure induced to the IW period. Lean proves the masked-denominator reindexing, the small/large optional split, and the original-minus-low decomposition. This supplies the exact same operator family required to combine the already checked comparison and changing-character maximal bounds.

Verification

All 934 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4553-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2581 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 936 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved. Sparse applications additionally record OrdinarySquareStoppingInput CS and IndependentPrimeMaximalInput as explicit independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion. Section7 additionally records the independent RawTaoArcConstructionInput C, used only to obtain actual finite IW frequency geometry. Its existence is unproved; multiplier, sampling, low and high norm estimates are not fields and remain unfinished.

Checkpoint_868_IWPageModelMaximum.md

Checkpoint 868: Quantitative IW comparison for the actual varying-Page circle model

The principal, fixed small-character and varying large-character comparison bounds are now assembled for the actual circle model. Lean constructs the fixed small datum from the given genuine Page data and proves a countable L2 majorant of size K*Q^(-1/4) for V_N minus the actual optional IW low symbol, on the same dyadic scales and with the original activity. This is the full circle-model high comparison,

conditional only on the already recorded general smooth multifrequency and raw Page inputs and the explicit starting budget. The prime-average approximation error, quantitative low Lp maximum and final restricted optimization still need their assembly.

Verification

All 935 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4554-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2582 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 937 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Proposition 4.19 consumes PrimeAsymptoticInputs, the refined PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. These are independent raw analytic/data hypotheses, not own-paper operator conclusions or new Lean axioms. Theorem 1.1 retains its separately recorded older fixed-scale inputs and independent ordinary-square global decomposition; reflection is proved. Sparse applications additionally record OrdinarySquareStoppingInput CS and IndependentPrimeMaximalInput as explicit independent analytic boundaries. Their existence and the exact normalization/support/sign adaptations remain unproved; neither predicate contains this paper's endpoint or sparse conclusion. Section7 additionally records the independent RawTaoArcConstructionInput C, used only to obtain actual finite IW frequency geometry. Its existence is unproved; multiplier, sampling, low and high norm estimates are not fields and remain unfinished.

`Checkpoint_869_IWPrimeApproximationMaximum.md`

Checkpoint 869: Actual prime approximation-error maximum with compatible Page data

The actual prime-square approximation error now has a uniform countable L2 maximum of size K*Q^(-1/2) from every permitted integer dyadic starting scale M. Lean obtains it from the already proved raw-data circle approximation with exponent two, sums the operator-norm decay, and retains the same selected Page datum at all scales. One positive range coefficient also guarantees genuine raw admissibility at every later scale, so the Page data used by the IW comparison and by the approximation are compatible. No IW low/high or restricted conclusion is assumed.

Section7 additionally records the independent RawTaoArcConstructionInput C, used only to obtain actual finite IW frequency geometry. Its existence is unproved; multiplier, sampling, low and high norm estimates are not fields and remain unfinished.

`Checkpoint_870_IWPrimeHighMaximum.md`

Checkpoint 870: Actual prime-square IW high maximal estimate with Q-to-minus-one-quarter rate

The actual von Mangoldt annular high operator is now constructed as the actual average minus the concrete IW low operator, with an exact operator decomposition. Lean combines the proved optional circle-model comparison with the compatible raw-data approximation error to obtain the full countable L2 high bound K*Q^(-1/4), including all prime powers and the varying Page character. The IW geometry is obtained from the independent raw Tao construction. The low measure identities are proved. The explicit residual source-range inequality is still stated here and will be absorbed into the sufficiently large exponential starting constant next. The quantitative low Lp maximum and actual restricted estimate remain unproved; this checkpoint does not assume either of them.

Section7 additionally records the independent RawTaoArcConstructionInput C, used only to obtain actual finite IW frequency geometry. Its existence is unproved; multiplier, sampling, low and high norm estimates are not fields and remain unfinished.

`Checkpoint_871_IWPrimeHighSourceScale.md`

Checkpoint 871: Actual prime high maximal estimate at the manuscript starting scale

The actual prime high-side estimate now holds under the manuscript's sufficiently large exponential starting scale, with no separate Q-range premise. Lean proves the uniform logarithmic cutoff implication and absorbs both the source-range and cutoff-difference requirements into one absolute starting constant. The conclusion constructs the genuine IW set and period, a permitted fixed small character, and the actual prime high operator with countable L2 majorant K*Q^(-1/4). Its independent assumptions are raw Tao construction, the existing generic smooth multifrequency theorem, raw Page uniqueness and compatible raw prime-distribution data. It does not use the new general IW multiplier boundary, assume the quantitative low maximum, or claim the actual restricted estimate. The ordinary-square companion and the low side are still open within the full source proposition.

Section7 additionally records the independent RawTaoArcConstructionInput C, used only to obtain actual finite IW frequency geometry. Its existence is unproved; multiplier, sampling, low and high norm estimates are

not fields and remain unfinished.

Checkpoint_872_AnnularMassVariation.md

Checkpoint 872: Uniform annular mass variation and reviewed prime high-side milestone

Lean now proves the exact zero-frequency mass factor for the actual annular model, its uniform bound by one, positivity and monotonicity in the scale, and uniform total variation at most one along every finite dyadic range. These are beta-uniform proved ingredients for the continuous signed-increment argument; the complete continuous Lp lemma is not claimed. This checkpoint also reviews the exact source statements against the checked prime high theorem at871: p:orlicz-hilo moves from open to partial only. The actual restricted estimate, low maximum and ordinary-square companion remain unproved. Documentation and recovery metadata are reconciled with the new scope and 54-claim inventory.

No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

Checkpoint_873_DyadicAbsoluteProfile.md

Checkpoint 873: Uniform absolute dyadic profile sum for the continuous increment argument

Lean now proves a uniform absolute geometric profile sum: sum over j<J of min(4^j*x,(4^j*x)^(-1))<=10/3 for every nonnegative x, including zero. A positive rational potential gives exact telescoping and avoids any unverified cutoff at a logarithmic index. The companion two-sided profile lemma converts the already proved annular small- and large-frequency estimates into this summable form. These

are proved scalar ingredients for the continuous signed-increment estimate; no low maximal conclusion is assumed.

`Checkpoint_874_AnnularAbsoluteError.md`

Checkpoint 874: Uniform absolute summation of the actual annular projection errors

The actual annular projection errors now have a proved uniform absolute dyadic sum, bounded by (10/3)*annularProjectionErrorConstant. The result permits beta to vary with the scale. Lean derives it from the existing actual small- and large-frequency bounds and the checked absolute geometric profile, including frequency zero. This strengthens the earlier square-energy bound in the form needed for the continuous signed-increment argument; no Lp low maximum is assumed or claimed.

`Checkpoint_875_SourceCutoffVariation.md`

Checkpoint 875: Uniform dyadic variation of the actual source cutoff

The actual smooth cutoff now has a proved uniform dyadic total-variation bound, at most 80/3. The proof uses only its checked core, support and range properties; it does not assume monotonicity of the chosen bump. Together with the absolute annular projection-error sum and the mass variation, this gives the three quantitative ingredients for the uniform continuous signed-increment multiplier bound.

`Checkpoint_876_ContinuousAnnularIncrements.md`

Checkpoint 876: Uniform beta-independent continuous annular signed-increment multiplier bound

Lean now proves a uniform bound for the actual continuous dyadic increments, first as a sum of absolute multiplier differences and then for arbitrary complex signed sums with coefficient norms at most one. The proof combines the actual mass variation, actual cutoff variation and absolute projection-error sums. The bound is independent of beta, frequency, number of scales and every integer starting scale M>=2. The initial N=1 scale and actual real-line operator realization are handled next; no Calderon-Zygmund or low maximal bound is used here.

`Checkpoint_877_ContinuousAnnularInitialIncrement.md`

Checkpoint 877: Continuous signed increments including the initial N-equals-one scale

The continuous signed-increment multiplier estimate now includes the actual N=1 starting term in the manuscript. Lean proves the uniform annular symbol bound at every N>=1, including the beta-uniform edge case, and combines the first increment with the checked later-scale sum. The resulting constant is independent of beta, frequency, length and complex signs. This completes the scalar multiplier preparation for a genuine Plancherel L2 operator bound; no general-p continuous or maximal theorem is assumed.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

Checkpoint_879_ContinuousAnnularKernel.md

Checkpoint 879: Actual continuous annular kernel, integrability and Hardy-Littlewood box bound

The literal continuous annular kernel is now a concrete real density supported on [N^2/4,N^2]. Lean proves its real and complex integrability, positivity and the uniform box bound by N^(-2) on [0,N^2] for N>=2 and beta<=1. This is the own-paper kernel bound needed to apply a precise general Hardy-Littlewood theorem; no continuous maximal estimate is assumed. Its exact Fourier-transform identity and uniform signed-kernel regularity remain subsequent obligations. The current canonical progress, statement review, independent-boundary and recovery reports have also been saved with the checked878 scope.

`Checkpoint_880_ContinuousAnnularKernelFourier.md`

Checkpoint 880: Exact Fourier identity for the literal continuous annular kernel

The literal annular kernel now has a proved exact Fourier-transform identity with the actual annular oscillatory multiplier. Lean checks the substitution t -> t^2, its derivative, both endpoints, the real/complex scalar normalization and the negative Fourier phase. The proof treats the kernel as an actual integrable function and uses the interval change-of-variables theorem; it does not assume the paper's kernel formula or continuous operator estimate. This connects the checked continuous L2 multiplier to the physical kernel needed by the remaining general-p argument.

Checkpoint_881_ContinuousAnnularKernelDerivative.md

Checkpoint 881: Uniform derivative bound for the actual continuous annular density

Lean now proves the derivative formula for the actual annular density and the uniform bound |K'_N(x)|<=4/N^4 on its annulus for 0<=beta<=1 and N>=2. The derivative is also identified exactly as (beta/2-1) times the density divided by x. Together with the checked support, box bound, integrability and exact Fourier identity, this supplies the own-paper local regularity data for the remaining uniform kernel argument. No full Calderon-Zygmund applicability, general-p increment estimate or low maximum is assumed or claimed.

`Checkpoint_883_IntervalKernelShiftGeometry.md`

Checkpoint 883: Translation envelope including both interval endpoint jumps

Lean now proves a general translation envelope for an interval-truncated kernel, explicitly including both endpoint jumps. A change in interval membership forces x into a collar of width 2|h| around one endpoint. For an inside bound B and inside Lipschitz constant L, the absolute translated difference is bounded pointwise by L|h| on the interval plus B on each endpoint collar. The result applies to arbitrary real densities; no annular maximal or Lp conclusion is assumed. The next step is to integrate this envelope and sum the dyadic scales.

Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_891_ContinuousAnnularSignedFourier.md`

Checkpoint 891: Exact Fourier identity for the actual signed annular kernel

Lean proves the exact Fourier transform of the literal complex signed annular kernel is the actual untruncated bounded signed-increment symbol used by the L2 realization. The proof supplies integrability of every summand, checks Fourier linearity, and invokes the already proved annular change-of-variables identity separately at both scales. Together with the checked uniform L2 bound and integral Hormander condition, this discharges all family-specific hypotheses for the independent scalar singular-integral theorem. No general-p bound is assumed or claimed at this checkpoint.

`Checkpoint_892_ScalarHormanderInterface.md`

Checkpoint 892: Full continuous signed-increment Lp implication from a general singular-integral theorem

Lean now proves the full actual continuous signed-increment Lp estimate for every 1<p<=2, uniformly in beta, the number of increments and arbitrary bounded complex signs, conditional only on an explicit general scalar Hormander singular-integral theorem. All family-specific integrability, exact Fourier, uniform L2 and endpoint-jump Hormander hypotheses have been proved. RawScalarHormanderInput C quantifies over arbitrary integrable kernels and their actual Fourier symbols; it contains no annular, IW, low/high, maximal or restricted conclusion. Its classical general existence and quantitative interpolation consequence are recorded as unproved independent analytic input, not Lean axioms. The second continuous maximal inequality, the quantitative IW low maximum and actual restricted maximal estimate remain unfinished.

`Checkpoint_893_ScaledCutoffL1.md`

Checkpoint 893: Actual cutoff kernels have invariant L1 norm and exact Fourier symbols

Lean checks the actual inverse-cutoff kernels at every positive dilation: integrability, the exact invariant L1 norm, and the exact forward Fourier transform eta(a theta). The invariant constant is the integral of the norm of the already constructed Schwartz inverse cutoff, so finiteness follows from the checked Schwartz integrability. A general positive real Fourier dilation identity is also proved from the existing inverse identity. This supplies concrete cutoff applicability data; it adds no analytic theorem input and does not assume a low or maximal bound.

Checkpoint_894_ContinuousAnnularConvolution.md

Checkpoint 894: Actual continuous annular convolution is dominated by one-sided interval averages

Lean now defines the actual continuous annular convolution using Mathlib's Lebesgue convolution and proves its measurability. For every L2 input and every point x, the literal annular convolution norm is bounded by the one-sided interval average of |f| over [0,N^2], for N>=2 and beta<=1. Local integrability of each reflected translate, integrability of the actual convolution integrand and the kernel box domination are proved explicitly. This is the family-specific applicability step for the independent general Hardy-Littlewood maximal theorem; that theorem has not yet been invoked. No current-paper maximal conclusion is an assumption.

Checkpoint_895_RealMultiplierComposition.md

Checkpoint 895: Composition and Lp product bounds for actual real Fourier multipliers

Lean proves composition of the actual real-line multiplication and Fourier-multiplier operators, including their almost-everywhere realization. It then proves the product rule for actual Lp multiplier bounds on

the L2 intersection, with output membership and the exact product of the two constants. These are algebraic/operator deductions from the checked Plancherel realization and extended-norm inequalities; no independent analytic theorem is added. This supplies the composition step for applying the invariant-L1 cutoff kernels to the actual continuous signed increments.

`Checkpoint_896_ContinuousAnnularMaximalInterface.md`

Checkpoint 896: Actual integer-scale continuous maximal Lp implication from general Hardy-Littlewood

Lean proves the actual countable continuous annular maximum over every integer N>=2 is in Lp with bound C/(p-1), for 1<p<=2, conditional only on the general one-sided Hardy-Littlewood maximal theorem. The input theorem ranges over arbitrary functions and all positive real interval lengths; it contains no annular or IW conclusion. Own-paper kernel domination, convolution integrability/measurability, simultaneous almost-everywhere domination of all integer scales, boundedness of the actual supremum and its Lp membership are checked. This includes all needed dyadic N>=2. The independent theorem existence is unproved, not a Lean axiom. The quantitative IW low maximum and actual restricted estimate remain unfinished.

`Checkpoint_897_AnnularFourierSmoothness.md`

Checkpoint 897: Actual annular C-infinity smoothness and corrected IW regularity interface

Lean proves integrability of every polynomial moment of the actual compact annular kernel, then proves the annular Fourier symbol, its source cutoff, and every bounded signed cutoff symbol are C-infinity. This checkpoint also corrects the IW interface's two regularity hypotheses from analytic top to C-infinity, as required by the independent theorem. The prior exact source and hashes are preserved; every other old proof source and all prior artifacts must remain authenticated. The changed module and all affected dependents are rebuilt before the full axiom audit. Seven negative/positive correction-validation cases pass. No prior nonzero use of the defective interface existed, and the actual prime high-side theorem does not use its predicate. No manuscript change or own-paper analytic assumption is introduced.

high/low conclusion are not external input fields.

Checkpoint_899_ContinuousAnnularCutoffLp.md

Checkpoint 899: Actual signed cutoff Lp bounds with a single near-one loss and initial-scale control

Lean proves the actual signed cutoff symbol factors exactly into the uncut signed symbol and source cutoff. Operator composition combines the checked continuous singular-integral implication with the invariant-L1 Young cutoff bound, retaining precisely one factor 1/(p-1), not an extra near-one loss. The actual annular kernel has integral norm at most 1 for every N>=1 and 0<beta<=1; Young therefore also supplies the actual individual annular and cutoff bounds, including N=1. No current-paper low maximum or restricted estimate is a premise. Independent general Hormander and Young theorem parameters remain explicit.

Checkpoint_900_IWSymbolLinearity.md

Checkpoint 900: Exact subtraction and finite-combination identities for actual IW symbols

Lean proves exact linearity of the literal compact periodization and actual cyclic IW symbols under subtraction and arbitrary finite complex linear combinations. The support hypotheses are explicit for every source and target symbol. The proof works directly with the periodization window and the actual

rational-frequency sum, retaining all cyclic Fourier coefficients. No norm inequality or independent analytic input is introduced. This supplies the exact identification between the forthcoming transferred signed multiplier and signed differences of the actual IW annular low family.

`Checkpoint_901_IWSignedAnnularBounds.md`

Checkpoint 901: Actual IW signed annular multiplier bound with explicit r times C_(r,k) dependence

Lean transfers the actual bounded smooth signed annular cutoff symbol through the corrected general IW multiplier theorem at p_r=(2r)'. It proves the exact narrow-support applicability, C-infinity applicability, positivity and near-one arithmetic, yielding the quantitative actual integer Lp bound K*r*C_(r,k), with K depending only on the recorded general scalar Hormander constant and the fixed cutoff L1 norm. The estimate is uniform in Q, the finite cyclic measure of variation at most one, beta, the number of increments and arbitrary complex signs. All output membership is explicit. Only the already recorded general IW, Hormander and Young parameters are used; no current-paper low maximum or restricted result is a premise. The exact signed-family identity and finite maximal deduction are next.

Verification

All 969 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4588-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2713 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 971 Lean files pass

the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_903_IWAnnularLp.md`

Checkpoint 903: Actual IW annular single-scale and signed-increment Lp bounds

Lean proves the single-scale actual IW annular Lp bound C_(r,k) times the invariant cutoff L1 constant for every N>=1, including the initial scale. It also proves the actual signed sum of consecutive IW annular low operators has Lp bound K*r*C_(r,k), with membership and extended-norm control, by the checked exact signed-family identity. These statements are uniform in beta and arbitrary finite cyclic measures of variation at most one. Independent general IW, Hormander and Young theorem parameters remain explicit; no source low maximum or restricted estimate is a hypothesis. The finite short-scale maximum and the narrow large-scale sampling argument remain next.

`Checkpoint_904_FiniteSignedMaximalInterface.md`

Checkpoint 904: Precise general finite signed-sum logarithmic maximal interface

Lean records the precise general finite-sequence Rademacher-Menshov/Khintchine maximal consequence needed for short scales, including actual membership, exact partial sums, arbitrary complex signs and the logarithmic dependence on sequence length. The independent theorem quantifies over arbitrary scalar sequences and contains no Fourier, arithmetic, annular or IW object. Its existence and the general probabilistic/dyadic argument are explicitly unproved, not Lean axioms. Separate checked lemmas identify the literal partial-sum maximum, its nonnegativity and domination. Instantiation for the actual IW increment sequence and addition of the initial term remain next.

`Checkpoint_906_FiniteDifferenceMaximum.md`

Checkpoint 906: Checked telescoping and Lp assembly of a finite family maximum from its increments

Lean proves a general finite-family maximal assembly from consecutive differences: exact telescoping, pointwise domination by the initial norm plus the partial-sum maximum, and the actual Lp membership and extended-norm triangle bound. This applies to arbitrary L2-valued sequences on the integers and uses only already formalized algebra, finite suprema and Lp inequalities. It introduces no independent analytic input. Combining it with the checked actual IW initial and increment bounds will yield the finite low-family maximum.

`Checkpoint_909_IWTransitionScale.md`

Checkpoint 909: Exact natural-ceiling transition index and dyadic scale bounds

Lean constructs the source dyadic transition index by the natural ceiling of -log(delta)/(2 log 2). It proves the exact ceiling bounds and the actual geometric scale inequalities 1<=N_*^2 delta<4 and 1<=N_* sqrt(delta)<2 for every 0<delta<=1. The log-two lower bound is also checked. This supplies the integer transition scale rather than treating an approximate real cutoff as a natural one. No analytic input, low maximum or restricted conclusion is assumed.

`Checkpoint_910_IWFiniteMaximumCost.md`

Checkpoint 910: Finite low maximum has the required r times C_(r,k) logarithmic cost

Lean simplifies the exact finite IW maximum cost to a universal constant times r*C_(r,k)*log(2+J), without an extra near-one or parameter loss. It also proves C_(r,k)>=1 in the actual admissible range, so the finite maximum can be compared with the source r*C_(r,k)^2 cost. These are explicit scalar deductions from the actual parameter definitions and the fixed cutoff norm, not asymptotic assumptions. The exact transition-index logarithmic budget and its substitution into the finite maximum are next.

<!-- checkpoint-verification -->

Verification

All 981 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4600-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2746 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 983 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_915_AnnularCutoffRemainderBounds.md`

Checkpoint 915: Actual cutoff remainder identities smoothness and L1/L2 endpoint bounds

Lean proves the actual original-minus-narrow annular cutoff remainder: exact nested-cutoff core and product identities, literal remainder factorization, uniform domination by the actual annular Fourier symbol, C-infinity smoothness, and the sharper L2 decay 4b/(pi N^2). The general-p rough bound 2*cutoffL1Constant follows from the checked individual Young bounds and actual operator subtraction; no own remainder norm is assumed. All endpoint applicability is now checked. Interpolation through the separately recorded general Riesz-Thorin theorem and subsequent IW transfer/summation are next.

`Checkpoint_916_AnnularCutoffRemainderLp.md`

Checkpoint 916: Actual annular cutoff remainder interpolation at the IW exponent

Lean proves the actual original-minus-narrow annular cutoff remainder at the near-one exponent p_r: the general Young endpoint and the checked sharper L2 decay interpolate to A (b/N^2)^(1/r), with the fixed explicit constant A=1+2*cutoffL1Constant+4/pi. The reciprocal interpolation identity, positivity, exact scalar power simplification and actual operator endpoint applicability are checked. Only the separately recorded independent general Young and Riesz-Thorin theorem hypotheses are used. IW transfer, summation and large-scale sampling remain unfinished; the actual restricted maximal estimate is not yet proved.

`Checkpoint_918_CountableLpMajorant.md`

Checkpoint 918: Countable Lp majorants from summable actual norms

Lean proves a general countable summation principle on the integers for every p>=1: if the actual eLp norms of arbitrary complex functions have finite total sum, their pointwise norm sum is a nonnegative real Lp function, dominates every term at every integer, and has eLp norm at most that total sum. The proof uses the pinned Mathlib Lp infinite-sum theorem, checks its hypotheses, and upgrades almost-everywhere identities to pointwise identities for counting measure. No external analytic theorem is added. This supplies the countable majorant required to sum the actual IW remainders, whose geometric scalar budget is being checked next.

`Checkpoint_919_IWRemainderGeometry.md`

Checkpoint 919: Exact IW transition geometry and summable remainder decay

Lean proves the full scalar geometry needed for countable cutoff-remainder summation. The actual narrow width has a positive inverse b, satisfies 2a<=b and b>=2, and its exact transition scale is at least two. At the literal scales 2^j*Nstar the interpolation factor (b/N^2)^(1/r) is bounded by exp(-1/r)^j; the geometric sum is at most 2r uniformly for integer r>=2. These statements use the already proved exact transition bounds, not an asymptotic replacement or a chosen unverified threshold. No external theorem is introduced. The next step combines this geometry with the checked actual integer IW remainder and countable Lp majorant.

`Checkpoint_920_IWRemainderMaximum.md`

Checkpoint 920: Actual countable IW cutoff remainder maximum

The actual large-scale IW original-minus-narrow remainder now has a countable nonnegative Lp majorant at every integer: all literal scales N=2^j*Nstar are dominated simultaneously, with eLp norm at most 2*A*r*Crk times the input norm. The proof combines the checked actual IW multiplier difference, exact narrow-width geometry, interpolation decay, the uniform geometric sum, and the general countable Lp theorem. It applies to every input in the L2/Lp intersection, not merely finite tests. No low maximal bound is assumed and no additional external analytic input is introduced. The finite short-scale K*D maximum is already checked; the narrow large-scale main term, full low estimate, and actual restricted estimate remain unfinished.

Checkpoint_921_IWSamplingSpaces.md

Checkpoint 921: Precise independent major-arc and finite-target Shannon sampling interfaces

Lean records precise independent sampling interfaces: scalar finite-cyclic Tao Theorem1.6 for arbitrary bandlimited Schwartz components and the finite-coordinate l-infinity specialization of Tao Proposition1.5 at width <=1/(100P). The normalized cyclic norm is explicit, as are actual diagonal values, exponent ranges, Fourier support and input membership. Lean proves the quantitative major-arc applicability wrapper from the checked IW goodness and periodic-denominator data, together with literal finite-coordinate maximum and synthesis identities. These general published sampling theorems are explicit hypotheses, not Lean axioms; neither contains an annular kernel or a current-paper low/high or maximal conclusion. The actual lift, its diagonal identity and the narrow large-scale application remain to be proved.

Checkpoint_922_IWFiniteLiftIdentity.md

Checkpoint 922: Exact periodized Fourier kernels and finite-input sampling identities

Lean proves exact Fourier identities needed for the concrete sampling lift: translating a circle symbol multiplies its integer inverse kernel by the correctly signed character; finite-symbol sums commute with the inverse kernel; the actual cyclic IW symbol has the literal finite sum of modulated real inverse Fourier kernels; and the multiplier on a finite input equals the inverse kernel of the symbol times the actual finite Fourier polynomial. Periodization also commutes with multiplication by a circle function after the proper rational shift. These are equalities of the existing operators, with no additional analytic assumption. Constructing the compact smooth lift amplitudes and identifying their diagonal with the actual cutoff projection are next.

Checkpoint_923_CyclicRealLpBounds.md

Checkpoint 923: Normalized cyclic Lp bounds and actual finite-cyclic Young inequality

Lean proves the normalized cyclic real-Lp norm inequalities used in the large-scale sampling argument: fibrewise norm comparison, invariance under cyclic translations, triangle inequality, scalar multiplication and finite sums. For the literal cyclic convolution of arbitrary Schwartz fibres, the resulting norm is at most the actual cyclic total variation times the original norm. The normalization is explicit, all relevant fibre memberships are checked, and no factor depending on the period is lost. These elementary analytic steps are proved rather than included in a new external input. The actual finite-input Fourier lift and narrow real-variable maximal application remain next.

`Checkpoint_924_FiniteSmoothFourierLift.md`

Checkpoint 924: Concrete smooth finite-input Fourier lift and actual IW projection formula

Lean constructs the concrete compact smooth Fourier amplitudes for every finite complex integer input and arbitrary smooth compact real symbol, and their actual inverse Schwartz transforms. Their Fourier transforms, support boundary, smoothness, periodization and rational-shift identities are checked. The existing integer IW multiplier on the finite input is exactly the finite sum of these modulated real lift components with the actual cyclic Fourier coefficients. This establishes the Fourier algebra needed for sampling, rather than assuming an intertwining identity. The cyclic residue diagonal identification, lift norm bound and narrow main-term maximum remain next.

`Checkpoint_925_CyclicLiftCharacters.md`

Checkpoint 925: Actual cyclic diagonal identification and quantitative finite-input lift bound

Lean proves the exact rational-character descent from integers to the finite cyclic group, including subtraction and the actual residue-valued diagonal. Cyclic convolution of the synthesis is identified with multiplication by the literal cyclic Fourier coefficients. The point mass has total variation and Fourier coefficients exactly one. Consequently the actual diagonal of the constructed finite-input lift is precisely the existing IW cutoff projection, and its cyclic convolution has the actual weighted IW projection as diagonal. Combining these identities with the separately recorded independent major-arc sampling and IW multiplier hypotheses gives the lift norm bound Crk^2*K times the finite-input norm. No intertwining or own low maximum is assumed. The narrow annular real-variable maximum and Shannon application remain unfinished.

Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_926_SchwartzMultiplierRealization.md`

Checkpoint 926: Actual Schwartz realization of real multipliers and cyclic norm transfer

Lean identifies the actual real L2 Fourier multiplier with the corresponding Schwartz function whenever their literal Fourier transforms agree. Its general Lp multiplier bound therefore controls the actual Schwartz representative, with both input and output almost-everywhere identities checked. Compact smooth multipliers are constructed on arbitrary Schwartz functions by their genuine inverse Fourier transform, their exact Fourier formula and Lp bound are proved, and the latter lifts to the normalized cyclic family norm. This removes a possible gap between abstract L2 operator norms and the pointwise functions later sampled. No additional external analytic input is introduced.

`Checkpoint_927_SchwartzConvolutionIdentity.md`

Checkpoint 927: Pointwise annular convolution identification for the sampled Schwartz functions

Lean proves that an integrable real convolution against a Schwartz function is exactly the Schwartz output whenever the literal Fourier transforms agree. The proof checks continuity, integrability, Fourier convolution and inversion, so it is pointwise rather than just an L2 identity. Applied to the actual annular kernel, this identifies its narrow-cutoff smooth multiplier with the actual annular convolution of the cutoff-filtered input. The cutoff and annular smoothness/support witnesses and finite-coordinate maximum continuity are proved explicitly. This supplies the final real-operator identification needed to apply the previously checked continuous maximal estimate to the narrow main term.

Checkpoint_928_SchwartzAnnularMaximum.md

Checkpoint 928: Actual narrow annular finite maximum on real and normalized cyclic Schwartz families

For arbitrary Schwartz inputs, Lean proves the literal finite maximum of the actual annular narrow-cutoff Schwartz outputs belongs to Lp and has norm at most (H/(p-1))*cutoffL1Constant times the input norm, uniformly over arbitrary finite collections of integer scales at least two and 0<=beta<=1. Its realization as the actual continuous annular convolution, finite maximum measurability, common Hardy-Littlewood majorant and Young cutoff cost are all checked. The estimate lifts to arbitrary normalized cyclic Schwartz families without any dependence on the number of scales or the period. Only the recorded independent general Hardy-Littlewood and Young inputs are used. The final narrow sampling and full low maximum assembly are next.

Checkpoint_929_SchwartzSynthesisMultipliers.md

Checkpoint 929: Exact multiplier synthesis and nested cutoff intertwining

Lean proves exact Fourier uniqueness on Schwartz space, the Fourier formula for the cyclic synthesis, its equality with actual cyclic convolution after inserting the cyclic Fourier coefficients, and the commutation of arbitrary compact smooth multipliers with a synthesis whose components satisfy the corresponding Fourier identity. The actual narrow annular symbol is proved to absorb the original wider cutoff using the checked nested-cutoff product identity. These exact algebraic steps supply the intertwining needed to turn the sampled narrow Schwartz outputs into the actual narrow IW operators; no sampling or maximal conclusion is assumed in their proofs.

`Checkpoint_930_IWNarrowLiftIdentity.md`

Checkpoint 930: Actual narrow IW operator as the diagonal of its annular lift

Lean proves the concrete narrow-lift intertwining: apply the actual annular narrow multiplier to the cyclic convolution of the original cutoff lift, and the result is exactly the cyclic convolution of the finite-input annular lift. On the actual diagonal (n,n mod P), this is precisely the existing narrow IW low operator on the finite input. The proof checks absorption of the original cutoff, rational characters, actual Fourier transforms and the genuine finite-input operator formula. The narrow output Fourier band is proved explicitly. Thus the functions to which the finite-target Shannon hypothesis will be applied are identified with the paper's operators, rather than treated as a generic unnamed model.

`Checkpoint_932_UniformFiniteLpMaximum.md`

Checkpoint 932: General uniform finite to countable actual Lp maximal extension

Lean proves a general uniform-finite-to-countable Lp maximal extension on the integers for every nonzero exponent, including infinity. A finite uniform extended-norm bound for every literal finite coordinate maximum yields one nonnegative actual Lp majorant dominating every member at every integer, with the same bound. Pointwise boundedness follows from counting-measure coordinate control; the convergence of finite maxima and the norm passage use the pinned Mathlib monotone-convergence and Fatou results with their hypotheses checked. No additional external theorem is introduced. This extends the newly checked narrow IW finite maxima to a genuine countable maximum.

`Checkpoint_935_IntegerLpMeasureBridge.md`

Checkpoint 935: Exact integer Lp norm bridge and indicator power budget

Lean proves the exact bridge between counting-measure Lp functions and the existing integer lp sequences at every positive finite exponent, including equality of the extended measure norm with the integer sequence norm. Finite complex inputs are thereby proved to satisfy every Lp membership hypothesis used by the actual low theorem. The exact indicator norm power is checked, and an actual Lp majorant bounded by K times the indicator input norm is converted into the finite power budget K^p*|F| required by the restricted-distribution argument. These are proved norm and membership identities, not additional independent inputs.

`Checkpoint_937_FiniteInputMaximalExtension.md`

Checkpoint 937: All-input extension and literal countable integer Lp maxima

Lean proves a general finite-input-to-all-input extension for countable families of actual bounded integer L2 operators. Finite inputs converge to the original L2 input, each finite output maximum is continuous, truncating the input does not increase its counting-measure Lp norm, and the checked Fatou and finite-to-countable principles preserve the exact maximal constant. This extends a proved finite-input maximal bound, not an independently assumed own-paper conclusion. The resulting all-input property implies the literal countable maximum bound and the standard integer lp formulation for every positive finite p<=2, using the exact counting-norm bridge and canonical integer lp inclusion into l2. No additional external analytic theorem is introduced.

Verification

All 1004 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4626-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2855 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1006 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full

high/low conclusion are not external input fields.

`Checkpoint_938_IWAllInputLowMaximum.md`

Checkpoint 938: Full actual natural-Q IW low maximum on all integer lp inputs

The natural-Q IW low estimate is now proved on all integer lp inputs at the near-one exponent, with a countable majorant of norm at most K*D(r,k,Q) times the actual lp input norm. The proved finite-input extension uses L2 continuity and Fatou; every integer lp input at p_r<=2 embeds canonically into l2, with exact counting-norm identification. The actual selected-Page prime low family also has its all-input maximal bound, with factor two. All own smoothness, Fourier, support, sampling, normalization and countable-limit obligations are discharged; the recorded general independent theorem hypotheses remain. The source ledger distinguishes the remaining printed real-Q/rough-symbol generality and the still unfinished actual restricted estimate.

`Checkpoint_939_MangoldtAnnularPositiveFamily.md`

Checkpoint 939: Actual positive dyadic annular von Mangoldt square averages

Lean constructs the actual positive dyadic annular von Mangoldt square-average family with its literal index interval, square shifts, normalization and all prime powers. The existing proved Chebyshev bound supplies its uniform mass; no prime number theorem is used. Every family member is identified exactly with the already formalized annular weighted-square L2 operator. This provides the concrete positive

maximal family to which the checked actual IW low/high bounds and the restricted-distribution lemma will be applied.

`Checkpoint_940_IWPrimeRestrictedDistribution.md`

Checkpoint 940: Actual prime annular restricted-distribution inequality from checked IW low and high bounds

The quantitative restricted-distribution inequality is now proved for the actual positive dyadic annular von Mangoldt square maximum, including all prime powers. Lean uses the actual source-scale high theorem to choose the same IW geometry and fixed Page datum, applies the checked all-input prime low bound, checks both indicator power budgets and the exact dyadic high reindexing, and invokes the proved union/Chebyshev argument. The result contains precisely the initial-scale t*J cost, the near-one low cost and the t^2*Q^(-1/2) high cost. No current-paper low/high or restricted-distribution hypothesis remains in this theorem; only the recorded independent general and arithmetic inputs do. The uniform parameter optimization to the printed near-one gauge, all-integer cutoff transfer and unweighted prime normalization are still unfinished.

`Checkpoint_941_IWRestrictedParameters.md`

Checkpoint 941: Explicit admissible integer parameters and endpoint losses

Lean verifies explicit integer parameter choices for every v>=1: r=ceil(v)+2, k=iwBalancedRank(v), and Q=2^(4r). Their rank and admissibility, r and k size bounds and the exact cutoff logarithm 2v<=log Q<=16v are checked. At v=nearOneLog(t), t>=1, the near-one exponent loss t^(p_r-1) is at most e and the high factor t*Q^(-1/2) is at most one; the full (2t)^p factor is at most 4e*t. These choices work uniformly including bounded t, so the scalar optimization does not rely on an unverified sufficiently-large range or rounding convention.

Checkpoint notes 942-1016

Checkpoint_942_IWOptimizedMultiplierCost.md

Checkpoint 942: Balanced-rank multiplier growth with explicit constants

Lean verifies that the balanced rank and rounded near-one order give log(C_{r,k}) <= C(log C+20) k log(e+v) uniformly for v>=1. It also checks 1<=sqrt(v log(e+v))<=2v and the corresponding exponential multiplier bound. These are scalar consequences of the previously proved explicit parameter choices; no new analytic theorem or optimization assumption is introduced.

`Checkpoint_948_IWPrimeAnnularRestrictedGauge.md`

Checkpoint 948: Actual prime annular restricted Orlicz estimate from the quantitative IW comparison

The actual dyadic annular von Mangoldt square maximal operator now satisfies the claimed restricted near-one Orlicz estimate for every finite indicator and every t>=1. Lean proves existence of nonnegative Cg and positive Rg and proves PositiveRestrictedGauge for the actual arithmetic family. It instantiates the concrete checked low/high distribution inequality at the checked integer parameters and starting index, applies the complete scalar budget and compares t*exp(Cg sqrt(log(e+t) log(e+log(e+t)))) with the integral gauge Psi. The paper-specific restricted estimate is a conclusion, not an independent hypothesis. The general IW, sampling, continuous, interpolation, Page and distribution inputs retain their explicit boundaries. The all-integer cutoff transfer and unweighted normalization are separate assemblies.

The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_949_PrimeCountingNormalization.md`

Checkpoint 949: Prime-counting normalization from checked Mathlib Chebyshev bounds

Lean derives the uniform lower bound N<=512*pi(N)*log N and its inverse-normalization form for every integer N>=2 from Mathlib Chebyshev.pi_ge. The finite small range is handled uniformly using pi(N)>=1; the large range uses a checked logarithm-square-root bound. This supplies the needed prime-counting normalization without adding PNT or a new independent input. It does not replace the separate stronger PNT hypotheses used earlier for the sharp Gauss asymptotic.

cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_950_IWPrimeFullRestrictedGauge.md`

Checkpoint 950: Actual full von Mangoldt restricted maximal and truncated modular estimates

The actual full von Mangoldt square maximal operator, taking the genuine supremum over every integer cutoff N>=2, now has the restricted Psi_C estimate. Lean transfers the proved annular estimate by the proved factor-four pointwise comparison and checked gauge doubling. It also instantiates the earlier restricted-to-modular proof: every finitely supported complex input has a finite actual superlevel set and the explicit truncated Orlicz cardinal bound. Thus the current-paper restricted bound is no longer an assumed premise for this arithmetic family. All independent general analytic and prime-distribution hypotheses remain explicit; this is a complete implication for the von Mangoldt family, not yet the full printed three-family Theorem7.2.

`Checkpoint_951_PrimeMangoldtSumComparison.md`

Checkpoint 951: Elementary weighted prime sums controlled by von Mangoldt partial sums

Lean proves an elementary comparison for every nonnegative weighted sequence: if all von Mangoldt partial sums up to m are at most m*B, then the prime sum up to N is at most 6*N*B/log N. The proof splits at floor(sqrt N), checks both prime logarithm bounds and the exact finite-sum inclusions. Combining it with the Mathlib Chebyshev normalization gives the normalized prime sum <=3072*B, for all N>=2. This is an elementary internal comparison, not a new analytic input.

`Checkpoint_954_CyclicFullSquareMeasures.md`

Checkpoint 954: The actual cyclic square measure for all integer residues

Lean defines the actual cyclic probability measure obtained by squaring every residue, including nonunits, with group-order normalization. Its test-function formula, total variation at most one, exact complete quadratic Gauss Fourier coefficient and norm-at-most-one bound are proved. This is the distinct measure needed for ordinary integer squares; the earlier unit-residue prime measure is unchanged. Workspace maintenance removed the compiler and dependency caches, so the exact pinned environment was restored and all 1020 recovered project modules plus the root were freshly compiled. All recovered Lean hashes agree with checkpoint953. The original compilation receipt is preserved, the process-path compatibility shim affects no Lean compiler/kernel code, and the new baseline and fresh complete audits are recorded. No ordinary restricted estimate or complete Theorem7.2 is claimed at this stage.

high/low conclusion are not external input fields.

`Checkpoint_955_CompleteQuadraticGaussBound.md`

Checkpoint 955: Complete quadratic Gauss bounds for arbitrary positive moduli

Lean proves the complete quadratic Gauss bound for every positive modulus and unit coefficient, including even moduli. The proof changes to difference/second coordinates, applies exact additive-character orthogonality and proves that the kernel of multiplication by two has at most two residues. Consequently the squared norm is at most 2q and the norm is at most 2 sqrt(q). This is elementary finite arithmetic proved in the project; no independent Gauss bound is assumed. It supplies the ordinary-square coefficient decay needed for the quantitative IW comparison.

`Checkpoint_956_CyclicFullSquareCoefficients.md`

Checkpoint 956: Exact ordinary-square coefficients and quantitative decay

Lean proves normalized complete Gauss decay, the actual rational ordinary-square coefficient and its exact equality with the Fourier coefficient of the full-residue cyclic square measure at every denominator dividing the period. Change of level follows from a proved finite additive-group pullback identity and the surjective residue map. The coefficient norm is at most one and its uniform denominator decay is at most 2*q^(-3/8), using the elementary Gauss bound at955. Thus the precise coefficient agreement, normalization and decay needed by both quantitative IW sides are checked, without an independent arithmetic input.

`Checkpoint_960_QuadraticWeylInput.md`

Checkpoint 960: Precise scalar Weyl boundary and proved rational-center uniqueness

Lean records a precise independent scalar quadratic Weyl approximation predicate and proves the rational-center uniqueness needed for its major-arc application. If the source center has denominator<=R, the selected denominator is<=8M, M lies between N/2 and N and 32R<=N, rational separation forces the selected center to equal the source center. The complete-Gauss half-power decay is also realized for the actual rational coefficient. The unproved scalar input, including its Dirichlet-selection/reduction/phase bridge to the published theorem, is described exactly in docs/SECTION_7_QUADRATIC_WEYL_BOUNDARY.md. It contains no own-paper circle sum, IW or maximal conclusion, and is not declared as a Lean axiom.

Verification

All 1027 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4649-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2942 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1029 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_961_QuadraticWeylArcBounds.md`

Checkpoint 961: Actual initial square major- and minor-arc bounds from the scalar Weyl input

From the explicit independent scalar Weyl input, Lean proves the actual initial-square major-arc approximation by forcing the selected rational center to agree with the source center. It also proves the full initial-square minor-arc bound, using the already proved complete Gauss decay and full oscillatory integral estimate, with exact denominator, square-root and relative-scale inequalities. The only new independent ingredient used is the scalar Weyl predicate documented at960; no own circle model, high maximum or restricted conclusion is assumed. These bounds hold uniformly for the two initial scales needed to form a dyadic annulus.

`Checkpoint_962_FullSquareRealCircleModel.md`

Checkpoint 962: Actual ordinary-square circle model and outside-arc bounds

Lean realizes the actual ordinary-square finite circle model with complete-Gauss coefficients. Each rational term has the proved outside-arc 1/sqrt(R) bound. Exact active-denominator counting gives the logarithmic finite-model bound, and the actual periodic circle model is identified with its five real lifts and bounded outside all source arcs. The periodization, cutoffs, canonical rational centers and denominator normalizations are retained exactly. No discrete circle approximation or maximal conclusion is assumed here.

Checkpoint_965_FullSquareApproximationRate.md

Checkpoint 965: Uniform logarithmic rate for the actual ordinary-square approximation

Lean proves a uniform source-scale bound for the actual ordinary annular Fourier approximation error: at every circle point the error is at most 4 Q^(-1/2) (1+log N)^(-2), for sufficiently large even N under log Q ≤ (1/8) sqrt(log N). The explicit major/minor and periodic model-tail budget is absorbed using proved logarithmic estimates. The geometric hypotheses are verified at the actual source radius, with the source parameter chosen to give the required cutoff range. This implication consumes only the declared independent scalar quadratic Weyl approximation for its arithmetic step; the paper-specific Fourier approximation is proved.

`Checkpoint_966_FullSquareApproximationMaximum.md`

Checkpoint 966: Countable L2 maximum for the ordinary-square approximation error

Lean proves an actual countable L2 maximal majorant for the ordinary-square circle-approximation error operators at all scales 2^j M, starting from a sufficiently large even M. The uniform logarithmic decay is converted to a summable dyadic operator-norm sequence; the nonnegative majorant has norm at most 8 (log 2)^(-2) Q^(-1/2) times the input L2 norm. The conclusion concerns the concrete discrete average minus the original varying-radius circle model, rather than an assumed approximation operator. The independent scalar quadratic Weyl hypothesis remains explicit.

`Checkpoint_967_IWFullSquareHighSourceScale.md`

Checkpoint 967: Actual ordinary-square IW high-term maximal bound

Lean proves the actual ordinary-square IW high term has a countable L2 maximal majorant of size K Q^(-1/4) at all annular scales 2^j M, once the source exponential starting-scale condition holds and M is even. It derives this result by adding the checked discrete circle-approximation error and the checked circle-model to IW-low comparison. All period instances, denominator geometry, cutoff widths and starting-scale thresholds are verified. The only new arithmetic input is the explicitly scoped scalar quadratic Weyl approximation; the source-specific high-term estimate and its maximal conclusion are proved, not assumed. This ordinary-square route does not consume the earlier ordinary-square global stopping decomposition input.

tinuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_969_IWFullSquareRestrictedDistribution.md`

Checkpoint 969: Restricted distribution from actual ordinary-square low and high estimates

Lean combines the actual ordinary-square IW low and high maximal bounds into a restricted distribution estimate for the full annular dyadic maximum. The proof checks indicator membership in the required near-one Lp space, Chebyshev power budgets, the scale reindexing above the chosen starting index and the exact decomposition of each concrete average. The finite initial range is estimated by positivity and mass one; its harmless enlargement to the previously optimized common mass constant permits reuse of the checked numerical parameter optimization. No ordinary-square restricted or maximal conclusion is assumed as an independent input.

`Checkpoint_971_OrdinaryFullAnnularComparison.md`

Checkpoint 971: Ordinary-square reconstruction for every integer cutoff

Lean proves the literal ordinary-square maximum over all integer cutoffs $N \geq 2$ is at most four times the actual ordinary annular dyadic maximum on indicators. The proof establishes the full-kernel cutoff comparison, the full-to-annular recurrence and its nonzero $N=1$ base case, and a genuine supremum bound. It then transfers the actual near-one restricted gauge through this comparison using the proved doubling estimate. This reconstruction is elementary and consumes no independent ordinary-square globalization or reflection assumption.

Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_972_IWFullSquareRestrictedGauge.md`

Checkpoint 972: Ordinary-square full restricted and modular estimates

Lean proves the actual ordinary-square restricted Orlicz gauge for the maximum over every integer cutoff $N \geq 2$. It combines the actual optimized annular estimate with the checked full-to-annular reconstruction, and deduces finite-cardinality restricted and truncated modular estimates for complex finitely supported inputs. This completes the ordinary-square companion needed for the three-family headline theorem. Its hypotheses are independent general IW/multiplier inputs and the precisely declared scalar quadratic Weyl approximation; neither an ordinary-square maximal conclusion nor the old global stopping decomposition is assumed.

Verification

All 1039 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4661-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 2985 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1041 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, both conclusions of Theorems 1.1 and 1.3, all displayed clauses of Proposition 4.19 and both clauses of Proposition 6.21 are complete checked implications under their separately recorded independent deep inputs. The square-sign reflection is proved. Theorem 1.3 has actual finite sparse families, disjoint major subsets and the literal full all-cutoff maximum. The three general Section5 auxiliary statements remain partial, and the later Orlicz/ergodic/sieve applications remain unfinished. Earlier Theorems1.1/1.3 and

Propositions4.19/6.21 preserve their separately recorded raw prime/distribution, Page, generic smooth multifrequency, ordinary-square and stopping hypotheses. Section7 additionally records RawTaoArcConstructionInput C and RawIWMultiplierInput C as explicit unproved independent general theorems, not Lean axioms. Actual geometry and full goodness and conditional smooth multiplier specialization are proved. The actual prime high-side comparison uses raw Tao construction, SmoothCircleBourgainInput, RawPageUniquenessInput and PagePrimeSquareDistributionInputs; its own coefficient identities, cutoffs, Page selection and approximation deductions are proved. General sampling and concrete continuous/low estimates remain unfinished. The current-paper low maximum, restricted estimate and full high/low conclusion are not external input fields.

`Checkpoint_973_IWThreeFamilyRestrictedGauge.md`

Checkpoint 973: Common restricted Orlicz constants for all three actual square families

Lean assembles actual restricted Orlicz bounds for all three manuscript families: von Mangoldt squares, ordinary squares and unweighted prime squares. It chooses common gauge and distribution constants at least one, proves the coefficient and multiplicative enlargements, and instantiates the actual family maxima. The ordinary branch is supplied by the newly proved scalar-Weyl-to-IW route; the prime branches use the previously checked prime-distribution route. This checkpoint proves the shared restricted estimate, while the final common truncated/unrestricted modular statement assembly is next.

`Checkpoint_974_SectionSevenThreeFamilyAssembly.md`

Checkpoint 974: One common set of constants for the three manuscript Orlicz conclusions

Lean proves the final source-shaped assembly from the actual shared three-family restricted gauges. It chooses one common enlarged gauge $C \geq 1$, one common truncation constant $C0 = 2$ times the checked uniform mass constant, and one common multiplicative constant $K \geq 1$. For each actual family it proves

finite level sets and all three manuscript conclusions: truncated modular, unrestricted modular and restricted. The proof checks the direction of the truncation inclusion and every nonnegative sum/constant enlargement. The internal gauge premise is already supplied by checkpoint 973; it is not a new independent theorem input. The raw-input wrapper and literal finite-support sums over the integers are completed next.

`Checkpoint_984_CorollarySevenSix.md`

Checkpoint 984: Complete source Corollary 7.6 for all three actual full maximal operators

Lean completes the source Corollary 7.6 for all three actual averaging families, every $1 < p \le 2$ and every integer lp input. One absolute constant is chosen before the family, p and input; the actual full maximal function belongs to lp and satisfies the exact displayed exponential norm bound. The proof derives it from Theorem 7.2 using checked layer cake, singular integral evaluation, all constant absorption and finite-input/Fatou extension. The source review upgrades c:orlicz-p from partial to complete conditional implication. No new independent input is introduced; the Theorem 7.2 boundaries remain explicit.

Verification

All 1051 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4673-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3008 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1053 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, Theorems 1.1 and 1.3, Propositions 4.19 and 6.21, and every clause of Theorem 7.2 are complete checked implications under their separately recorded independent inputs. Theorem 7.2 covers all three actual square families, every integer cutoff N >= 2, arbitrary complex finite support, common constants, actual finite level sets and truncated, unrestricted modular and restricted estimates. The square-sign reflection is proved. The stronger standalone auxiliary ranges and later deductions retain their separately reviewed scopes. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation

(including its unproved published-theorem selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative high/low comparisons, restricted estimates, parameter optimization and final source assembly are proved. No such own-paper conclusion is an independent input. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs. The full-square global/local stopping hypotheses for the earlier theorems are not used by the new ordinary-square IW route.

`Checkpoint_985_ErgodicSquareAverages.md`

Checkpoint 985: Actual ergodic square averages and a proper extended countable maximum

Lean defines the actual ergodic positive averages for an invertible measurable transformation, using the exact integer action and all three source families. It proves the positive square-iterate specialization, measurability, linear difference identity and uniform bounded-function estimate. The countable ergodic maximum is defined in the extended nonnegative reals, with every average dominated unconditionally; finite real-valued norm claims will explicitly include an almost-everywhere finiteness certificate. This prevents an unbounded supremum from collapsing under a conditional real supremum convention.

The full-square global/local stopping hypotheses for the earlier theorems are not used by the new ordinary-square IW

route.

Checkpoint_986_ErgodicIndependentInputs.md

Checkpoint 986: Precise independent general transference and bounded-class convergence interfaces

Lean implements precise independent general strong and modular Calderon transference predicates and the independent bounded-class square convergence predicate. The strong interface retains the actual discrete all-input norm and requires almost-everywhere finiteness of the proper extended ergodic maximum. The modular interface ranges over arbitrary continuous nonnegative gauges and actual finite-input distribution bounds. The bounded-class input contains its explicitly unformalized published-theorem and normalization bridge and asserts no unbounded Orlicz result. A checked application lemma exposes the exact strong transfer. These are unproved independent hypotheses, not newly formalized published theorems or new Lean mathematical axioms.

No such own-paper conclusion is an independent input. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs. The full-square global/local stopping hypotheses for the earlier theorems are not used by the new ordinary-square IW route. The ergodic route now records precise general strong/modular Calderon interfaces and a bounded-class polynomial pointwise interface, including its unproved published-theorem and PNT/Abel/prime-power normalization bridge. No unbounded Orlicz or source prime-enumeration endpoint is assumed; these remain deductions to prove.

Checkpoint_987_ErgodicStrongMaximal.md

Checkpoint 987: Actual ergodic strong maximal bound with the source quantitative rate

Lean transfers the proved actual Corollary 7.6 to the actual ergodic maximal operators for all three families, with exactly the same exponential p dependence. One constant is chosen before the probability system, family, exponent and function. For every $1 < p \le 2$ and every Lp input, the conclusion includes almost-everywhere finiteness of the proper extended maximum, actual Lp membership of its real representative and the stated norm bound. Only the explicit independent general strong Calderon

theorem is newly consumed; no source-specific ergodic norm estimate is assumed. The modular and Orlicz convergence clauses remain subsequent deductions.

`Checkpoint_988_ErgodicModularMaximal.md`

Checkpoint 988: Actual ergodic modular inequality from the general transference input

Lean proves the actual ergodic modular maximal inequality from the already proved Theorem 7.2 and the explicit independent general modular Calderon input. It converts finite counting cardinalities correctly, proves the discrete modular premise for the exact gauge (including any later coefficient enlargement), and applies transfer to the proper extended ergodic maximum. The conclusion uses the actual nonnegative gauge integral for every positive level and every a.e. strongly measurable complex function. The Orlicz truncation/convergence argument is not assumed and remains the next analytic deduction.

`Checkpoint_989_PrimeCutoffEnumeration.md`

Checkpoint 989: Exact prime-counting and enumeration sum identities

Lean proves the exact arithmetic bridge between prime cutoffs and prime enumeration: pi(p_(k+1)) = k+1, pi(N) > 0 for N ≥ 2, the finite prime set is the injective image of the corresponding range under Nat.nth Prime, and sums over primes equal sums over that range. The result uses actual Mathlib prime counting and infinite prime enumeration and checks every index, with no PNT, asymptotic or enumeration hypothesis. This supplies the concrete normalization and sum identity required for Theorem1.5(ii).

`Checkpoint_992_OrliczTruncation.md`

Checkpoint 992: Orlicz truncation, integrability and vanishing tail at every positive scale

Lean defines bounded truncations and the exact measurable Orlicz class, and proves equivalence with finiteness of the nonnegative gauge integral at some positive scale. It proves pointwise vanishing of the

truncation tail, the gauge rescaling bound at every fixed positive level, L1 integrability from Psi(t) ≥ t, and dominated convergence of the actual tail modular integral to zero. Thus the density approximation required by Corollary7.46 is proved rather than assumed, including the scale change justified by the checked doubling/rescaling estimate.

`Checkpoint_993_OrliczMaximalCauchy.md`

Checkpoint 993: Own Orlicz density argument giving almost-everywhere Cauchy convergence

Lean proves the own Orlicz density/Cauchy deduction. It defines the actual tail-oscillation obstruction, proves that a Cauchy bounded approximant excludes that obstruction whenever the actual error maximum is small, bounds its measure by each truncation-tail modular integral and lets that integral tend to zero. A countable sequence of positive thresholds then gives almost-everywhere Cauchy convergence of the original averages. The maximal bound and bounded-class Cauchy facts are internal premises to be supplied by the proved modular transfer and the explicitly independent bounded-class theorem; no unbounded Orlicz convergence is an external input. L1 convergence is the remaining analytic deduction.

`Checkpoint_994_ErgodicL1Operators.md`

Checkpoint 994: Actual ergodic L1 operators, representative agreement and uniform norm

Lean constructs the genuine L1 continuous linear ergodic square-average operators from measure-preserving iterates, proves their almost-everywhere agreement with the actual source averages, checks invariance under almost-everywhere changes of the input, and handles arbitrary L1 representatives. It proves the uniform operator norm bound by the actual averaging mass. Thus the uniform L1 continuity needed for the density argument is proved from positivity and measure preservation, rather than added as an independent input.

`Checkpoint_995_L1TruncationApproximation.md`

Checkpoint 995: Checked bounded truncation density in the actual L1 space

Lean proves bounded truncations preserve L1 integrability, that their actual L1 tail norms tend to zero by dominated convergence, and that the corresponding actual L1 equivalence classes converge to the original input. The proof checks both pointwise representatives and quotient-space distances, and exports an approximation sequence with almost-everywhere agreement with every literal truncation. No density or L1 approximation theorem is assumed independently.

Verification

All 1062 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4684-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3050 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1064 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The ten completed source results under their paper hypotheses remain unchanged. Lemma 3.21, Theorems 1.1 and 1.3, Propositions 4.19 and 6.21, and every clause of Theorem 7.2 are complete checked implications under their separately recorded independent inputs. Theorem 7.2 covers all three actual

square families, every integer cutoff N >= 2, arbitrary complex finite support, common constants, actual finite level sets and truncated, unrestricted modular and restricted estimates. The square-sign reflection is proved. The stronger standalone auxiliary ranges and later deductions retain their separately reviewed scopes. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved published-theorem selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative high/low comparisons, restricted estimates, parameter optimization and final source assembly are proved. No such own-paper conclusion is an independent input. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs. The full-square global/local stopping hypotheses for the earlier theorems are not used by the new ordinary-square IW route. The ergodic route now records precise general strong/modular Calderon interfaces and a bounded-class polynomial pointwise interface, including its unproved published-theorem and PNT/Abel/prime-power normalization bridge. No unbounded Orlicz or source prime-enumeration endpoint is assumed; these remain deductions to prove.

`Checkpoint_996_BoundedL1Cauchy.md`

Checkpoint 996: Bounded pointwise Cauchy convergence implies actual L1 Cauchy convergence

Lean proves the bounded L1 Cauchy criterion on a finite measure space: an almost-everywhere Cauchy sequence of actual L1 functions with a common almost-everywhere pointwise bound is Cauchy in L1. The proof applies dominated convergence to all pairs of indices, checks the product filter and actual L1 quotient distances, and concludes the full Cauchy property. This is the bounded-class L1 step required by the ergodic density argument; no bounded L1 convergence or density-extension theorem is assumed independently.

The ergodic route now records precise general strong/modular Calderon interfaces and a bounded-class polynomial pointwise interface, including its unproved published-theorem and PNT/Abel/prime-

power normalization bridge. No unbounded Orlicz or source prime-enumeration endpoint is assumed; these remain deductions to prove.

`Checkpoint_997_UniformOperatorDensity.md`

Checkpoint 997: Uniform continuous-operator density argument for full L1 convergence

Lean proves the general uniform-operator density argument in normed spaces: a uniformly bounded sequence of actual continuous linear operators is Cauchy on an input whenever it is Cauchy on a sequence of approximants converging to that input. It checks the full two-index Cauchy condition and quantitative approximation errors. Applied to the proved L1 ergodic operators and bounded truncations, this supplies the unbounded L1 convergence extension without assuming that conclusion as an independent theorem.

The ergodic route now records precise general strong/modular Calderon interfaces and a bounded-class polynomial pointwise interface, including its unproved published-theorem and PNT/Abel/prime-power normalization bridge. No unbounded Orlicz or source prime-enumeration endpoint is assumed; these remain deductions to prove.

`Checkpoint_998_OrliczErgodicConvergence.md`

Checkpoint 998: Actual Orlicz almost-everywhere and L1 convergence with the same limit

Lean completes the own Orlicz pointwise and L1 convergence deduction for the actual ergodic averages. It applies the exact bounded-class independent input to every checked truncation, proves L1 Cauchy convergence on the bounded class by dominated convergence, extends through the actual uniformly bounded L1 operators and truncation density, and obtains a genuine L1 limit. A convergent subsequence in measure and the proved almost-everywhere Cauchy property identify the full pointwise limit with that same L1 limit. Actual integrability of every average, vanishing L1 seminorm and vanishing integral norm of the difference are explicit. No unbounded Orlicz or L1 density-extension conclusion is an independent input. The remaining final step is common-constant/source assembly for Corollary7.46.

`Checkpoint_999_CorollarySevenFortySix.md`

Checkpoint 999: Complete source Corollary 7.46: quantitative ergodic bounds and Orlicz convergence

Lean completes the full source Corollary7.46 for all three actual ergodic square families. One common positive constant governs the quantitative strong exponential rate and Orlicz gauge, with a common modular multiplier fixed before all systems, families, functions and levels. The proper extended maximal function has almost-everywhere finiteness, actual Lp membership and the source norm and modular bounds. Every member of the literal Orlicz class at some positive scale has actual averages converging almost everywhere and in L1 to the same genuine L1 limit; every average is integrable, and both the L1 seminorm and integral norm of the difference tend to zero. Own truncation, scale-change, tail-oscillation, L1 operator, density, completion and limit-identification deductions are proved. General strong/modular transference and bounded-class convergence, including their unformalized published-theorem/normalization bridges, remain precise independent hypotheses; none asserts unbounded convergence or an own-paper endpoint. Corollary7.6 was completed at984 and Theorem1.5(ii) at991. Theorem1.5(i) remains open, so the whole Theorem1.5 remains partial. The manuscript is unchanged, and each checkpoint retains separate build, audit, integrity and save evidence.

Verification

All 1066 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4688-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3056 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1068 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

Theorem7.2, Corollaries7.6/7.46 and Theorem1.5(ii) are complete checked implications under their explicitly recorded independent inputs. This includes the actual full maximal operators, quantitative strong and modular bounds, own Orlicz pointwise/L1 convergence and exact prime enumeration. Theorem1.5(i) remains open, so its whole source entry is partial. Earlier Theorems1.1/1.3, Propositions4.19/6.21 and reflection retain their reviewed scopes. Stronger standalone auxiliary statements and later arithmetic applications remain separately unfinished. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route.

`Checkpoint_1000_UnitSquareResidues.md`

Checkpoint 1000: Actual unit-square residues, CRT and prime representation

Lean defines the actual unit-square residue sets, proves their exact equivalence to unit squares, their CRT multiplicativity and nonemptiness, and proves that every such residue is represented by an actual enumerated prime square. The prime representation uses the pinned Mathlib Dirichlet theorem itself, with no new independent hypothesis. This begins Section 8; the correlation, spacing, auxiliary modulus and persistent-badness assemblies remain to be proved. All earlier checkpoint999 conclusions and their independent boundaries are preserved.

`Checkpoint_1003_FiniteSpacingCounterexample.md`

Checkpoint 1003: Exact counterexample and recorded Section 8 spacing repair obligation

Lean certifies an exact rational counterexample to the general strict fraction inequality quoted from LaVictoire Lemma3.2 and used in the source Section8 proof. For the normalized circle configuration coming from {0,1,2,4} modulo6, theta=1/10 and J=12, the claimed left fraction is1/4 and its lower bound is1/2. The kernel checks the actual cyclic gaps and all four far-point proportions; no floating-point or native evaluation is used. This identifies a repair obligation, not a counterexample to persistent badness. SECTION_8_SPACING_CORRECTION.md records the details. The manuscript is unchanged, and the badness conclusion remains unclaimed until a correct replacement argument is proved.

Theorem1.5(i) remains open, so its whole source entry is partial. Earlier Theorems1.1/1.3, Propositions4.19/6.21 and reflection retain their reviewed scopes. Stronger standalone auxiliary statements and later arithmetic applications remain separately unfinished. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route.

`Checkpoint_1006_QuadraticCorrelationWeilBound.md`

Checkpoint 1006: Actual k-point quadratic correlation from the general Weil estimate

Lean derives the actual k-point nonzero-quadratic-residue correlation from the independent general split-polynomial Weil estimate. For every finite set S of distinct shifts it proves the explicit bound abs(N(S)-p/2^card(S)) <= 2*card(S)*sqrt(p). The full subset expansion, all finite character sums, empty-set constant, powerset count and exact zero corrections are checked. No own residue-correlation estimate is an independent hypothesis. The relative density normalization and c=1/3 GK format remain the next step.

`Checkpoint_1008_QuadraticCorrelationRelative.md`

Checkpoint 1008: Exact local-density normalization and relative quadratic correlation

Lean proves the exact local density formula and normalizes the absolute quadratic correlation. It checks the finite power main-term shift, proves abs(N(S)-r_p^card(S)*p) <= 3*card(S)*sqrt(p), and proves the explicit relative error abs(N(S)/(r_p^card(S)*p)-1) <= 3*card(S)*3^card(S)/sqrt(p). Positivity of all normalizing factors and every denominator cancellation are checked. The only independent input is the already recorded general Weil character-sum estimate.

Checkpoint_1012_QuadraticTripleMoment.md

Checkpoint 1012: Uniform actual quadratic triple moment with the zero-shift exception checked

Lean proves the actual uniform three-variable additive residue moment by summing the checked pair correlations over the third variable. It isolates and bounds the unique possible zero-shift exception, with all density and square-root comparisons checked. The triple count is at most (1+63/sqrt(p))*card(Lambda_p)^3/p for every target residue; both pair and triple counts are then bounded with the common coefficient64. These conclusions are derived from the general Weil input and are not new independent hypotheses.

`Checkpoint_1016_GlobalQuadraticMomentBound.md`

Checkpoint 1016: Actual global quadratic moments from the checked local error budget

Lean proves that a sum budget for the actual local Weil errors bounds the full prime-product pair and triple counts by three times their random-model expressions. The argument checks finite product/exponential bounds, exact CRT count factorizations and exact model normalization. It proves pair <= 3*card(Lambda_q)^2/q for shifts nonzero at every block prime, and triple <= 3*card(Lambda_q)^3/q for every target. The finite error budget is an explicit ordinary hypothesis to be supplied by the proved large-prime block construction, not an independent analytic input.

Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3153 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1085 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

Theorem7.2, Corollaries7.6/7.46 and Theorem1.5(ii) are complete checked implications under their explicitly recorded independent inputs. This includes the actual full maximal operators, quantitative strong and modular bounds, own Orlicz pointwise/L1 convergence and exact prime enumeration. Theorem1.5(i) remains open, so its whole source entry is partial. Earlier Theorems1.1/1.3, Propositions4.19/6.21 and reflection retain their reviewed scopes. Stronger standalone auxiliary statements and later arithmetic applications remain separately unfinished. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route.

Checkpoint notes 1017-1091

Checkpoint_1017_CyclicThickening.md

Checkpoint 1017: Actual cyclic thickening, translation counts and exact rounding

Lean defines the actual cyclic thickening as the finite union of positive integer translates, with the exact open-interval convention and no limiting model substituted. It proves exact translation/intersection cardinality identities, the exact natural-ceiling membership condition, the one-unit rounding bounds for the number of allowed shifts and the genuine probability bounds on the thickening density. These unconditional finite statements supply the discretization step of the Section8 repair.

Checkpoint_1018_CyclicThickeningMomentBound.md

Checkpoint 1018: Actual cyclic thickening deficit from finite pair moments

Lean proves the actual cyclic thickening estimate from its finite pair counts, without a spacing-distribution hypothesis. If the actual allowed translates have pair intersection cost at most

C*card(S)^2/q, their thickening density lies between gamma-card(S)/q-(C/2)*gamma^2 and gamma. The exact integer rounding, positive normalizations, finite union count and every quadratic inequality are checked. The actual prime-product application will supply the pair-count premise from the already proved Weil/CRT estimates.

`Checkpoint_1019_PrimeProductThickening.md`

Checkpoint 1019: Actual prime-product thickening bound with every pair premise discharged

Lean applies the finite thickening theorem to the actual unit-square residue sets of prime products. The global pair bound is supplied by the proved Weil/CRT moment theorem; the exact small-shift hypothesis is checked by injectivity of natural residues below every block prime. Under the finite error budget and explicit radius bound, the actual density lies between gamma-rho_q-(3/2)*gamma^2 and gamma. No spacing distribution, Poisson limit or thickening conclusion is an independent input. The constructed blocks still need to supply the elementary budget and radius conditions.

`Checkpoint_1020_CyclicNearShifts.md`

Checkpoint 1020: Exact cyclic near-pair covering by signed integer shifts

Lean proves exact signed-integer shift cardinalities and a kernel-checked covering of the actual near-difference pairs by triple-count events. It proves that every short cyclic distance is represented by an integer shift in the precise floor-bounded interval, including zero and either direction around the circle. Far and near cardinalities partition the full ordered pair set. No general spacing inequality is assumed.

`Checkpoint_1021_CyclicDifferenceMomentBound.md`

Checkpoint 1021: Actual far-pair lower bound from the checked cyclic triple-count cover

Lean proves the genuine far-pair fraction is between zero and one and derives its quantitative lower bound from the actual triple moments. With moment coefficient C, the fraction is at least1-2*C*gamma-C*card(S)/q. The proof checks the exact near/far partition, covers every short cyclic distance by a signed integer shift, bounds the finite union and verifies the positive normalization. No finite-spacing fraction lemma is assumed.

Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route.

`Checkpoint_1027_BadnessSpacingLimits.md`

Checkpoint 1027: Actual source liminf thickening deficit and difference condition

Lean passes the actual constructed-block moment estimates to the source real liminf conditions, using the proved density limit and explicit boundedness. The thickening deficit is nonnegative and at most (3/2)*gamma^2 for0<gamma<=1. The actual far-pair liminf is at least1-6*gamma and strictly exceeds5*(1/160) whenever0<gamma<1/16. Every statement concerns the literal unit-square sets for the constructed moduli. The little-o formulation is the next short analytic step.

Verification

All 1094 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4884-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3208 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1096 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

Theorem7.2, Corollaries7.6/7.46 and Theorem1.5(ii) are complete checked implications under their explicitly recorded independent inputs. This includes the actual full maximal operators, quantitative strong and modular bounds, own Orlicz pointwise/L1 convergence and exact prime enumeration. Theorem1.5(i)

remains open, so its whole source entry is partial. Earlier Theorems1.1/1.3, Propositions4.19/6.21 and reflection retain their reviewed scopes. Stronger standalone auxiliary statements and later arithmetic applications remain separately unfinished. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route.

`Checkpoint_1028_BadnessThickeningLittleO.md`

Checkpoint 1028: Full source little-o thickening condition for the actual constructed moduli

Lean proves the exact source little-o thickening condition for the actual constructed unit-square sets. It sends the deficit divided by gamma to zero on the positive-side neighborhood of zero using the checked quadratic deficit bound, then proves the genuine IsLittleO statement with the denominator's nonvanishing condition explicit. Together with the prior source difference condition, all density/thickening/difference limiting hypotheses are now proved under the general Weil input, without Poisson spacings or the refuted strict finite inequality.

`Checkpoint_1029_UniformUnitSquareFibers.md`

Checkpoint 1029: Exact uniform fibers of squaring on units

For every positive modulus, Lean proves that all fibers of squaring on the finite unit group over its image have equal size. The explicit multiplication bijection identifies each fiber with the kernel. Summing the fibers gives kernel size times the actual unit-square image size equals Euler totient. Consequently each unit-square class has exactly the fraction 1/|Lambda_q| of all unit residues. This includes composite moduli and supplies the exact normalization for prime-square frequencies without any exceptional-prime approximation.

`Checkpoint_1030_PrimeSquareFrequency.md`

Checkpoint 1030: Exact prime-square residue frequencies from fixed-progression PNT

The actual frequency of the nth-prime squares in every unit-square residue class is proved to converge to 1/|Lambda_q|, for every positive modulus. The only new independent input is the standard fixed-progression PNT formulated for frequencies of enumerated primes in individual unit classes. Lean proves the exact disjoint root-class partition of the finite counts, sums the finite limits, and applies the checked uniform-fiber identity. It also proves the strict beta=1/2 liminf condition and strict increase of the actual prime-square sequence. No prime-square equidistribution conclusion is assumed as an input.

`Checkpoint_1032_SequenceBadnessMaximal.md`

Checkpoint 1032: Proper sequence maximal operator and pointwise divergence

Lean defines the literal complex ergodic averages along an arbitrary sequence and the proper extended-real maximum over any set of cutoffs. It proves measurability, the exact identity with the maximum along the increasing enumeration of an infinite cutoff set, and that an infinite maximum prevents convergence to any finite complex limit. Nonatomicity is defined by measurable splitting of every positive-measure set; the deprecated Mathlib NoAtoms alias only means null singletons and is deliberately not used. These deductions contain no external mathematical input.

`Checkpoint_1033_PersistentBadnessCriterion.md`

Checkpoint 1033: Persistent badness from independent general weak maximal principles

Lean proves the full persistent-divergence adaptation of the original arithmetic badness theorem. The independent inputs are separately quantified general original LaVictoire weak-maximal failure, Sawyer maximal principle, and same-constant Conze transference. The proof uses contraposition to produce an integrable measurable function whose proper maximum is infinite on a measurable positive-measure set, then proves divergence along the increasing enumeration of every infinite set of cutoffs. It applies to truly nonatomic ergodic measure-preserving probability systems without assuming invertibility. The current paper's adapted criterion and prime-square badness are deductions, not input fields. The published general theorems and their precise Lean formulation/convention bridges remain unformalized.

`Checkpoint_1034_TheoremOneFive.md`

Checkpoint 1034: Prime-square persistent badness and both parts of Theorem 1.5

Lean proves Theorem1.5(i) for the actual sequence of enumerated prime squares: every nonatomic ergodic measure-preserving probability system, every infinite set of cutoffs, a measurable integrable complex function and a measurable positive-measure set of pointwise divergence. Its independent inputs are the general split-polynomial Weil bound, fixed-progression PNT frequencies, original LaVictoire weak maximal theorem, Sawyer maximal principle and Conze transference; their existence and published-to-Lean convention bridges remain unproved. It also assembles both parts of Theorem1.5 with the already checked quantitative Lp conclusion of part(ii), retaining all of that part's existing independent inputs. The corrected spacing proof is used, and Granville–Kurlberg is not needed for this badness deduction. Source-level status review and exact replacement TeX remain before closing the Section8 milestone.

IW route.

Checkpoint_1036_GranvilleKurlbergInterface.md

Checkpoint 1036: General GK boundary and actual unit-square joint Poisson application

The quoted Granville–Kurlberg theorem now has a precise general interface: arbitrary CRT residue families, actual local correlations with a common positive exponent and constants chosen before primes and shifts, subpower reciprocal density, odd squarefree moduli and growing mean spacing imply full joint cyclic Poisson spacings. Its proof and published-to-Lean cyclic/joint formulation bridge remain unproved and explicitly external. Lean verifies every local and modulus hypothesis for the actual unit squares, proves the constructed block moduli squarefree, and derives joint Poisson convergence and the source single-gap tail exp(-theta) conditional on that general input and the Weil input. The completed prime-square badness theorem does not depend on this optional Poisson input.

Checkpoint_1037_OddSquarefreeUnitSquareFormulas.md

Checkpoint 1037: All odd-squarefree image, root and mean-spacing formulas

For every odd squarefree modulus, Lean proves the exact image cardinality |Lambda_q|=phi(q)/2^omega(q), exactly 2^omega(q) unit roots of every unit-square class, and the mean-spacing product over prime divisors. It first proves the finite prime-product totient identity and then passes to the literal prime-factor set of any odd squarefree modulus, including q=1. These proofs complete the remaining elementary cardinality clauses of Section8 and require no independent analytic input. Together with the already saved Theorem1.5 assembly, only final source-statement review, replacement-proof documentation and report synchronization remain for this milestone.

Verification

All 1104 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4895-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3249 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1106 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

Theorem7.2, Corollaries7.6/7.46 and Theorem1.5(ii) are complete checked implications under their explicitly recorded independent inputs. This includes the actual full maximal operators, quantitative strong and modular bounds, own Orlicz pointwise/L1 convergence and exact prime enumeration. Theorem1.5(i) remains open, so its whole source entry is partial. Earlier Theorems1.1/1.3, Propositions4.19/6.21 and reflection retain their reviewed scopes. Stronger standalone auxiliary statements and later arithmetic applications remain separately unfinished. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route.

`Checkpoint_1038_SectionEightMilestone.md`

Checkpoint 1038: Section 8 and Theorem 1.5 complete conditional milestone with checked proof repair

Checkpoint1038 closes Section8 and Theorem1.5(i) as complete checked conditional implications and retains the combined theorem for both parts of Theorem1.5. The final literal statement displays actual prime-square iterates and normalized finite sums, every truly nonatomic ergodic probability system, every infinite cutoff set, a measurable integrable function and a measurable positive-measure divergence set. The adapted criterion is proved from separately specified original LaVictoire, Sawyer and Conze

inputs; Weil and fixed-progression PNT supply general arithmetic inputs, while every own-paper arithmetic/moment/limit/frequency deduction is proved. The quoted general GK theorem remains unproved, with a precise joint Poisson interface and checked application that badness does not use. The exact source review updates only the two completed source claims. A Lean kernel counterexample identifies the strict finite-fraction error, and the checked moment replacement is supplied as both a proof passage and complete Section8 TeX with an insertion guide. The replacement compiles in isolated LaTeX; the hashed manuscript is unchanged. Final complete build, source audit, transitive theorem axiom audit, source-level registry validation and archive checks are required before this checkpoint is saved.

Verification

All 1105 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4896-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3252 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1107 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

Both parts of Theorem1.5, the adapted LaVictoire criterion and the full Section8 own-paper deductions are complete checked implications under separately recorded general independent inputs. The actual prime-square badness proof uses Weil, fixed-progression PNT, original LaVictoire, Sawyer and Conze; their existence and published-to-Lean convention bridges remain unproved. All arithmetic, moment, limiting, frequency and persistent-divergence deductions are proved. The quoted general GK theorem remains unproved with a precise interface and checked joint Poisson application; it is not used by badness. The source strict finite-fraction proof requires the saved exact TeX replacement. The frozen manuscript is unchanged. Earlier headline, maximal, sparse and Orlicz scopes remain as reviewed. Stronger standalone auxiliary ranges and Sections9–11 remain separately unfinished. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure, Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

Checkpoint_1039_SectionSixSourceExports.md

Checkpoint 1039: Confirmed Section8 edits and full source approximation and low estimates

The user-confirmed three Section8 edits are recorded as applied in a new selected project manuscript reconstructed from the exact agreed passages; original files are preserved, all numbered statements and labels are unchanged, and no new full upload is claimed. The Sections3–8 source review finds twelve partial auxiliaries in Sections5–7. This checkpoint closes two of them: the full source approximation lemma and the full low-contribution proposition. Lean exports the literal selected error with exact Q^(-1/2)*(1+log N)^(-A) operator and all-l2 function norms for every A>0, with one source coefficient chosen before A. It also exports one uniform constant for the actual low operator's all-real-radius local bound and l1-to-linfinity norm, for every complex l1 input and real Q in the standing source range. Existing compatible raw distribution inputs remain explicit; no new general mathematical input is added. Ten other auxiliary claims, including a sparse-recursion statement requiring scale qualification, remain before Goldbach work.

Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

Checkpoint_1040_RealAnnularKernelBounds.md

Checkpoint 1040: Literal annular kernels at every real scale

Lean extends the actual continuous annular density and kernel to every positive real scale, with exact agreement at natural scales. It proves integrability, nonnegativity and the uniform box-kernel bound for every real N>=2, uniformly in beta<=1. This removes the first integer-scale restriction in the standalone continuous auxiliary lemma. The full uncountable maximum and its measurability, common almost-everywhere bound and Lp estimate are separate next deductions; this checkpoint does not prematurely award the full source lemma. No independent input is used for these real-scale kernel proofs.

All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

Checkpoint_1041_RealAnnularConvolution.md

Checkpoint 1041: All-input real annular convolution and continuity in scale

For arbitrary Lp inputs with p>=1, Lean proves the real-scale annular convolution is measurable and dominated pointwise by the one-sided interval average. It checks the literal kernel-to-interval integral identity and proves continuity in the real scale parameter at every spatial point, using a locally integrable clamped power weight and continuous interval primitives. These facts enable a fixed countable dense set of real scales to represent the proper uncountable maximum, rather than interchanging uncountably many almost-everywhere assertions. No external input is used in this checkpoint.

All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

Checkpoint_1042_RealAnnularMaximal.md

Checkpoint 1042: Proper all-real-scale annular maximum on the full Lp domain

The proper maximum over every real N>=2 is now proved measurable by equality with one fixed countable dense set of scales, using the checked scale continuity. For every actual Lp input with 1<p<=2, Lean proves a common almost-everywhere bound for all real N, almost-everywhere finiteness of the extended-real maximum, Lp membership of its finite representative and the exact near-one norm bound. The standard one-sided Hardy–Littlewood input is stated on its full Lp domain; this general theorem remains unproved and contains no annular or current-paper conclusion. Its restriction to the earlier L2-intersection interface is proved. Integer box averages and an exact ceiling comparison avoid an uncountable union of exceptional sets. No paper-specific maximal conclusion is assumed. The full source continuous lemma will be reviewed only after its signed-multiplier clause and exact kernel/Fourier identification are assembled.

Checkpoint_1044_FullContinuousSource.md

Checkpoint 1044: Complete source continuous annular lemma on all Lp inputs and real scales

The entire printed continuous annular lemma is now a checked conditional implication. One positive constant precedes beta,p,J,signs and every Lp function. The actual signed-increment convolution has the

exact source multiplier and a uniform near-one bound on the full Lp domain. The proper maximum over every real N>=2 is measurable, finite almost everywhere, belongs to Lp and satisfies the same near-one rate. All annular Fourier, L2, Hormander, scale-continuity and dense-supremum deductions are proved. The general Hardy–Littlewood and scalar Hormander theorems are stated in precise full-domain forms and remain unproved independent inputs; no source-specific estimate is assumed. The source review changes only this auxiliary claim to conditional, leaving nine partial auxiliaries before Goldbach work.

`Checkpoint_1045_LinearLocalMass.md`

Checkpoint 1045: Literal linear-scale admissibility and exact finite window counts

The literal linear-scale local average and its supremum over every real radius are now formalized on actual l1 inputs, with convergence, positivity at positive scales and uniform bounds. For indicator inputs Lean proves the exact finite window-count formula and exports the source admissible dyadic stopping-map condition as an equivalence with its displayed all-real-radius finite-count inequality. This supplies the missing concrete admissibility objects for the general Section5 argument. No analytic or own-paper

conclusion is an assumed input. Completion of the definition's additional convention remarks is not claimed here.

`Checkpoint_1046_LocalErrorSquareMaximum.md`

Checkpoint 1046: General local error maximum at the sharp square-summability threshold

Lean proves the countable l2 error maximum from the source's full assumption A>1/2. The proof uses square summability of the logarithmically decaying dyadic operator norms, not the stronger and unjustified requirement that their norms be summable. It constructs an actual nonnegative l2 majorant

dominating every scale pointwise and proves its norm bound with a finite constant depending only on A. This is the general error ingredient for the complete abstract localized stopping lemma. The current work plan is regenerated from exact pending source labels at each checkpoint, and the confirmed Section8 edits remain recorded.

Verification

All 1113 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4904-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3295 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1115 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The user confirmed the three Section8 edits; the selected project manuscript contains their exact agreed reconstruction, with all numbered statements and labels unchanged and original sources preserved. Sections3/4 and Section8 retain their complete reviewed conditional scopes. The full approximation lemma and low proposition of Section6 are now exported with exact real-Q, all-input, all-real-radius and exponent quantifiers. Remaining Sections5–7 auxiliary claims are being reviewed and completed before Goldbach work. Deep general inputs remain explicit and unproved. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure, Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1047_HighLowCappedBalance.md`

Checkpoint 1047: Exact endpoint optimization on the full bounded density range

The general local endpoint optimization is extended from density at most one to every fixed bounded density range. Lean keeps the exact printed density and logarithmic exponents, handles densities above one by the splitting parameter J=2, and proves one constant uniform over all densities below the fixed cap. This is needed because support in a fixed dilation cI permits $|F||G|/|I|^2$ above one. It closes that normalization issue in the general Section5 argument without silently imposing a smaller density range or changing its exponents. No independent analytic input is used.

`Checkpoint_1048_LocalStoppingHypotheses.md`

Checkpoint 1048: Exact hypotheses and small scales for the abstract stopping lemma

The full abstract local hypotheses are encoded as bounds on the actual operator family, its low/high/error pieces, and the real-radius linear local average. The record contains neither a stopping pairing estimate nor an endpoint conclusion. The physical scale is 2^j, the splitting threshold is exactly (10J)^(s/(1-v)), and Lean proves the small-scale estimate with the printed powers of J and log J. This exposes the full mathematical assumptions needed for the general Section5 local argument rather than replacing it by the already-proved prime-square instance. No analytic input or new axiom is introduced.

`Checkpoint_1049_LocalStoppingTradeoff.md`

Checkpoint 1049: The finite stopping tradeoff with actual square-summed errors

Lean proves the full low/high/error tradeoff for a family with uniform local hypotheses. The actual stopped output is split pointwise into the original small-scale contribution and the decomposed large-scale contribution. The high and error pieces are controlled by genuine l2 majorants; the error uses the square-summation theorem valid for every A>1/2. The resulting finite pairing bound is uniform over the stopping map and splitting parameter. The localized, single-indicator formulation in the printed lemma still needs its own export: the present record has stronger bounds uniform over indicators, so this supporting result alone is not counted as completing the source lemma.

`Checkpoint_1050_LocalizedStoppingTradeoff.md`

Checkpoint 1050: Localized hypotheses with uniform constants in the stopping argument

The tradeoff is now proved with the hypotheses localized exactly as needed in the source: local and low bounds are required only for the current indicator F and only on the testing set G. The common input constant is an explicit parameter, so subsequent endpoint constants are uniform over the sets and the chosen operators. No bound for unrelated indicators or points is assumed. The proof constructs and masks actual high and error outputs and uses genuine l2 majorants. This removes a possible quantifier gap between a convenient uniform-family supporting lemma and the printed local statement. No independent analytic input is introduced.

`Checkpoint_1051_AbstractLocalStoppingEndpoint.md`

Checkpoint 1051: The complete localized abstract stopping endpoint with exact exponents

The abstract local stopping endpoint is proved for every v<1, s>0, r>0, gamma>=beta>=0 and A>1/2, with exactly the source density and logarithmic exponents. One output constant is chosen before the interval length, sets, stopping map, and localized operator data; it depends only on the displayed fixed parameters, a common input bound and the fixed density cap. Empty sets, densities above one, every stopping map, and the localized low hypothesis are handled. No current-paper conclusion is an input. The remaining source export is the precise radius/scale/convolution convention bridge, not the endpoint inequality or its optimization.

`Checkpoint_1052_LinearLocalRadiusComparison.md`

Checkpoint 1052: All-real-radius comparison for the admissibility conventions

The all-real-radius local average is now compared across arbitrary fixed positive radii. Lean proves that replacing C0 by C costs at most max(1,C/C0), by enlarging each real scale and checking both the window inclusion and the change in normalization. This supplies the missing admissibility-radius bridge in the abstract local stopping lemma. The proof holds for every l1 input, not merely finite indicators, and uses no external analytic theorem.

`Checkpoint_1053_SourceAbstractLocalStopping.md`

Checkpoint 1053: The physical-scale and radius export of the abstract local lemma

The source conventions for the abstract stopping estimate are now exported: physical dyadic values are recovered exactly from their exponents, arbitrary positive admissibility radii are compared, support size in a fixed dilation is replaced by its explicit uniform density cap, and the parent interval length is the normalization. Lean proves the exact equivalence of the source splitting range J<=M^((1-v)/s)/10 with the threshold used by the proof and identifies M^(1-v) times the local average with the literal M^(-v) window count. The terminal source endpoint has the printed exponents and a constant chosen before all interval, set, stopping and operator data. A final Fourier-symbol-to-operator bridge is being added before awarding the printed source lemma completion.

`Checkpoint_1054_SourceLocalStoppingFourier.md`

Checkpoint 1054: Completion of the full abstract local stopping lemma

The full abstract local stopping lemma l:localsparse is now matched to the source and proved under its printed hypotheses. The error symbol is an arbitrary circle function bounded almost everywhere, rather than a smooth or continuous restriction: Lean proves its operator norm from the actual integer Fourier isometry. The terminal theorem chooses one constant before all intervals, sets, physical dyadic stopping maps, operators and symbols, and has exactly the printed density and logarithmic exponents. It covers every A>1/2, localized low assumptions, arbitrary positive admissibility radii, all real radii, empty sets and densities above one. No own-paper conclusion or new independent analytic input is assumed. The reviewed registry now records 11 proved claims, 14 complete conditional implications, eight partial auxiliaries, one quoted external theorem and 20 open later claims. Section9 has not been started.

`Checkpoint_1055_LinearOneSidedAdmissibility.md`

Checkpoint 1055: Exact one-sided admissibility comparison and a saved clarification

An exact Lean check resolves the one-sided convention attached to admissibility. Each one-sided window count is bounded by the symmetric count, and the symmetric count is at most the sum of the two directions. A singleton F={-1} at x=0 has zero forward local averages at every real radius M>=1, while its symmetric local average is at least one. Thus a single fixed direction cannot be interchanged pointwise merely by multiplying constants. A precise replacement using the maximum of both one-sided local averages is saved separately; it is not silently applied. The full abstract local stopping lemma uses the symmetric condition and remains proved. No new external input is used.

Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3322 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1124 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The user confirmed the three Section8 edits; the selected project manuscript contains their exact agreed reconstruction, with all numbered statements and labels unchanged and original sources preserved. Sections3/4 and Section8 retain their complete reviewed conditional scopes. The full approximation lemma and low proposition of Section6 are now exported with exact real-Q, all-input, all-real-radius and exponent quantifiers. Remaining Sections5–7 auxiliary claims are being reviewed and completed before Goldbach work. Deep general inputs remain explicit and unproved. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure,

Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1056_VariableAdmissibilityPairings.md`

Checkpoint 1056: Uniform stopping pairings for every fixed admissibility constant

The ordinary-square stopping pairing and endpoint, and the actual prime large-scale pairing, are extended from the convenient fixed admissibility constant 320 to every fixed B0>=1. Lean checks the dependence of all output constants before the interval, sets and stopping map. The original independent ordinary-square low/high input already allowed arbitrary B0, so no stronger external input is introduced. This removes a genuine source-range restriction in the prime-square local auxiliary rather than merely rescaling the final statement.

`Checkpoint_1057_VariableAdmissibilityPrimeEndpoint.md`

Checkpoint 1057: Prime-square local assembly with an arbitrary fixed admissibility constant

The full small/large-scale prime-square stopping assembly now works for every fixed admissibility constant B0>=1, retaining the sharp leading Orlicz coefficient cstar>4 sqrt(3)/9. All constants are chosen uniformly before the interval, finite sets and spatially varying dyadic scales. It uses the existing independent ordinary-square decomposition and the checked actual Proposition4.19, with no new external theorem input. The next export changes the parent normalization and covers arbitrary fixed support dilations and spatial radii.

`Checkpoint_1058_ParentEndpointRescaling.md`

Checkpoint 1058: Parent-interval geometry and full-density Orlicz rescaling

Lean proves the fixed-density rescaling needed to express the prime local endpoint using the parent interval length. The Orlicz comparison now covers target densities both below and above one, preserving

the sharp leading coefficient. It also constructs enlarged parent intervals, proves their support inclusions and proves the exact density relation. These are geometric and scalar deductions; no analytic estimate is assumed or modified.

`Checkpoint_1059_QuadraticLocalRadiusBridge.md`

Checkpoint 1059: Exact quadratic-scale admissibility for arbitrary fixed spatial radii

The literal quadratic-scale admissibility condition is identified with the linear local average at the squared lower scale, using every real radius and the exact square-root inverse substitution. Lean then deduces the source radius-one bound from the printed condition with any fixed positive spatial radius C, with the explicit factor max(1,1/C). The finite window counts and normalization M^-2 are exact. This supplies the spatial-radius bridge for the general prime-square local endpoint without restricting the printed radius to a convenient value.

`Checkpoint_1060_GeneralParentPrimeEndpoint.md`

Checkpoint 1060: Arbitrary support dilations and the exact parent-normalized prime endpoint

The prime-square local endpoint now has the literal parent-length normalization and allows every fixed support dilation. The proof embeds the original parent in a fixed larger interval, converts its admissibility constant exactly, and compares the resulting densities and Orlicz factors without changing the leading coefficient. It retains a larger reference test set, so restricting to the nonzero stopping scales does not assume monotonicity of an Orlicz bump. The operator remains the actual annular von Mangoldt square average. No new independent input is introduced.

`Checkpoint_1061_PhysicalDyadicPrimeStopping.md`

Checkpoint 1061: The physical dyadic scales including the zero contribution at scale one

Lean verifies the exact reindexing from the physical dyadic stopping values used in the manuscript to the implementation's scales 2^j*2. Scale1 contributes exactly zero for the actual von Mangoldt kernel. The full physical pairing is therefore exactly the pairing over the test subset where the stopping value is at least2; no norm inequality or density monotonicity is substituted for this identity. Empty input sets are covered as well. This closes the final scale-convention issue for the source prime-square local endpoint.

`Checkpoint_1064_RealIWConstruction.md`

Checkpoint 1064: The real-Q IW construction and exact-width smooth applications

The actual Ionescu-Wainger geometric construction is now proved for every real Q>=2^k. The proof uses floor(Q) only for the integer denominator range and retains the exact real-Q formulas for B and epsilon. Lean verifies P<=3^Q, coverage, denominator and component bounds, and actual goodness at the narrower width. It also proves the existing smooth multiplier and scalar Schwartz inverse-sampling applications at that exact width throughout p_r<=p<=2r. The broader rough-symbol/full-class/two-direction/vector-valued sampling clauses and the exact-real-width full low maximal assembly remain explicitly partial. No new deep input is introduced and no stronger source status is awarded without its proof.

Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure, Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1065_AuxiliaryScopeCertificates.md`

Checkpoint 1065: Consolidated pre-Goldbach source review with exact scope certificates

The pre-Goldbach source review is consolidated with exact Lean scope certificates. A nonnegative density profile disproves the blanket fixed-dilation comparison for arbitrary Psi in the sparse-recursion proof; the corrected dyadic recursion can retain the displayed dilated form, but still needs its proof. Two scalar certificates show why a logarithm-squared estimate cannot be relabeled as a first-power estimate by changing a constant. They do not assert a counterexample to the special sharper annular theorem. The source review records five newly completed numbered auxiliaries, seven precise remaining claims, the exact real-Q IW extension, and the separately proposed one-sided admissibility clarification. Section9 has not been started. No new independent analytic input is introduced.

Verification

All 1132 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4923-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3361 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1134 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The user confirmed the three Section8 edits; the selected project manuscript contains their exact agreed reconstruction, with all numbered statements and labels unchanged and original sources preserved. Sections3/4 and Section8 retain their complete reviewed conditional scopes. The full approximation lemma and low proposition of Section6 are now exported with exact real-Q, all-input, all-real-radius and exponent quantifiers. Remaining Sections5–7 auxiliary claims are being reviewed and completed before Gold-

bach work. Deep general inputs remain explicit and unproved. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure, Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1066_LinearGoodPointMass.md`

Checkpoint 1066: Accepted source conventions and general linear-scale stopping geometry

The accepted admissibility, dyadic sparse-scale, retained-dilation and factor-four passages are reconstructed in a new selected source. All labels and all other numbered statements are preserved; no new full manuscript upload is claimed. The corrected admissibility definition and both comparison directions are now fully formalized, including the exact factor two. Lean also proves the linear-scale good-point estimate and all-real-radius admissibility of the remaining stopping scales, for arbitrary fixed kernel radius C, directly from the checked elementary interval-packing construction. These are the geometric inputs to the general positive-kernel sparse recursion, not an assumed sparse conclusion. Seven numbered auxiliaries still await their complete source exports. No new analytic input or axiom is introduced.

All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1067_GenericDyadicKernels.md`

Checkpoint 1067: General positive dyadic kernels and arbitrary fixed support dilations

An arbitrary positive dyadic convolution family is now represented by its actual kernels with only positivity and compact spatial support as fields. Lean constructs every fixed odd interval dilation and proves its nesting and kernel localization, including repeated restriction from a parent to a stopping child. The dilation may be chosen for any fixed real kernel radius; no prime-square structure or analytic decomposition is assumed. These source-level support deductions are used next in the general sparse recursion. No new independent input is introduced.

`Checkpoint_1069_GenericSparseLinearization.md`

Checkpoint 1069: Whole-set admissible linearization without a monotone density profile

The remaining maximum is linearized on the whole testing set, without discarding points or assuming that Psi is monotone. Where the remaining index set is empty, the stopping map uses the largest dyadic scale below the interval length; Lean proves that this default scale is admissible. Positivity then gives the required pairing inequality on the entire testing set. The local input is only the source stopping-time estimate, with its sufficiently large fixed admissibility constant explicit. No maximal or sparse conclusion is introduced as an input.

Checkpoint_1070_GenericFiniteSparse.md

Checkpoint 1070: General finite sparse recursion for an arbitrary density profile

The general finite sparse recursion is proved from the local stopping-time hypothesis for arbitrary positive compact-support dyadic convolution families. The output has actual intervals and disjoint major subsets of at least three quarters their lengths. The exact density-profile cost uses F intersected with the fixed dilation and G intersected with the parent, divided by the parent length. Psi is arbitrary: no positivity, monotonicity or dilation-comparison property is added. Every recursive call shortens the interval, so termination and the cost sum are checked. Removing the outer scale truncation remains a separate proof step.

Checkpoint_1071_GenericKernelTesting.md

Checkpoint 1071: Finiteness of the full maximum deduced from the local testing hypothesis

The local hypothesis itself now supplies a uniform bound for every finite-indicator output at every dyadic scale and spatial point. Lean proves translation invariance of the actual convolutions, compares each output with a dense interval test, and applies the local estimate to that dense test at its full parent scale. The resulting bound is K Psi(2m+1,1), independent of the indicator and scale. Thus finiteness of the full maximum is derived rather than assumed. No positivity or monotonicity condition on Psi is introduced.

`Checkpoint_1072_GenericFullMaximum.md`

Checkpoint 1072: The untruncated dyadic maximum and a finite testing reduction

The full untruncated dyadic maximum is now a bounded real supremum, with boundedness derived from the local testing estimate. For every finite testing set, Lean selects finitely many dyadic scales whose maximum dominates at least half the full pairing. This handles suprema that need not be attained and removes the need for an unproved compactness or monotone-limit argument for sparse families. The finite selection is proved for the actual kernel outputs, and Psi remains arbitrary. No new independent input is introduced.

`Checkpoint_1073_GenericFullSparse.md`

Checkpoint 1073: The full general dyadic sparse implication with an arbitrary density profile

The general untruncated dyadic sparse implication is proved for every positive compact-support convolution family and arbitrary density profile. Lean constructs a finite root containing the input, testing points and the finitely selected scales, applies the terminating recursion, and obtains actual quarter-sparse major subsets. The constant is exactly twice the local testing constant and is uniform over all finite input and testing sets. No monotone Psi, scale decay, attained infinite maximum, limiting sparse family, or current-paper sparse conclusion is assumed. The final wrapper still checks the source convention that stopping maps are admissible on the entire parent interval.

Checkpoint_1074_GenericSourceSparse.md

Checkpoint 1074: Complete general sparse deduction with full-domain admissibility and explicit constants

The full generic dyadic sparse implication is proved from the normal local stopping hypothesis, with admissibility required on the entire parent interval. An explicit extension by a large default scale proves the needed local restriction without enlarging the hypothesis or assuming a monotone Psi. The full maximum is finite by a proved dense-testing argument, and an actual quarter-sparse finite family controls it with constant2K. One source-notation refinement remains: the window radius and sufficiently large RHS admissibility constant must be independent; A>=320max(1,C) is a sufficient explicit choice. Its exact LaTeX is saved separately, and the source claim stays conservatively partial pending that clarification. No new deep input is introduced.

Verification

All 1141 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4932-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3400 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1143 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The accepted Section8, admissibility, dyadic sparse-scale and retained-dilation edits are reconstructed in the selected manuscript, with original source copies and every label preserved. Only the accepted definition and dyadic auxiliary statement change inside numbered environments; no new full user upload is claimed. The seven remaining auxiliaries are being proved from their normal source hypotheses and the explicitly recorded independent standard inputs. No own-paper conclusion is a new deep assumption. Section9 has not been started. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure, Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1075_AnalyticIWLow.md`

Checkpoint 1075: Low maximal proof under its precise analytic data requirements

The full IW low maximal proof is now checked for an analytic data structure requiring only positive pairwise coprime components, a common period, its size bound, and the component bound. Rational coverage is not a hypothesis of this analytic theorem. Twenty-two existing deductions have been generalized and freshly compiled, from goodness and multiplier/sampling estimates through the narrow, transition, remainder, finite-input, and all-input maximal estimates. This introduces no external input. The original arithmetic construction and its coverage theorem remain available separately; this separation will allow the exact real-Q cutoff to be retained rather than rounded. The full paper proposition is not claimed complete at this intermediate step.

The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1076_RealIWBase.md`

Checkpoint 1076: Exact real-parameter width through a proved change of universal constant

Monotonicity in the universal IW constant is proved for the quantitative multiplier constant and for the two independent multiplier/sampling inputs. For real Q>=1 and k>=4, an adjusted constant between C and C^2 converts the natural parameter ceil(Q) to exactly the real-Q denominator bound with universal constant C^2. The denominator bound and the cutoff width agree identically, not merely up to an inequality. The exponent and ceiling estimates are checked, and no additional analytic assumption has been introduced.

`Checkpoint_1077_RealIWAnalyticData.md`

Checkpoint 1077: Arithmetic data and cost at the exact real-Q width

The original floor-Q arithmetic construction is now converted to the weaker analytic data at ceil(Q), using the adjusted universal constant. The rational set and the period are unchanged. Its component bound, period bound, and exact real-Q width are checked. The complete natural-Q low cost at the adjusted base is bounded by twice the literal real-Q cost at base C^2. The proof keeps the exact logarithm and checks all signs, ceiling estimates, and the universal-constant comparison. Rational coverage through the original real Q is still supplied by the floor construction.

`Checkpoint_1078_RealIWLowMaximum.md`

Checkpoint 1078: Complete all-input low maximal bound at the literal real-Q width

The exact real-Q dyadic low family now has its full countable maximal bound on the L2/Lp intersection and on every integer lp input at p=p_r. The arithmetic set and period are the original floor-Q construction; the width is exactly the displayed real-Q width, with universal parameter constant C^2. The bound is twice the original universal low constant times the literal real-Q cost. A proved monotonicity step transports the independent standard multiplier and sampling inputs to the adjusted constant. The all-input extension and canonical inclusion into L2 are reused with all applicability checked. No new deep hypothesis or current-paper conclusion is assumed.

`Checkpoint_1079_RealIWSourceLow.md`

Checkpoint 1079: Complete real-Q source low proposition with its arithmetic construction

The real-Q geometric construction and the exact actual all-input low maximal estimate are now assembled in one theorem. It gives period<=3^Q, coverage of all rational denominators<=Q, the literal denominator bound and goodness, and the countable low estimate uniformly for all allowed measures and beta. The fixed universal parameter constant is enlarged from C to C^2; monotonicity of the independent Tao construction is proved as well. The paper registry now records p:orlicz-low as a complete conditional implication. No own low/maximal conclusion is assumed, and no new external theorem or Lean axiom has been introduced. The remaining broader IW and high-side statements are not awarded credit by this step.

`Checkpoint_1081_RealIWHighLowAssembly.md`

Checkpoint 1081: Real-Q low and high estimates for one shared arithmetic construction

The complete high estimates have been strengthened and checked for every valid arithmetic construction, so the prime and ordinary-square comparisons can use exactly the same set and period. Their common real-Q assembly is now proved at the literal real-Q width and exponential starting scale, with the required negative-quarter-power rate for the sum of both high norms. The original general multifrequency, Page, distribution and quadratic-Weyl inputs remain explicit. Independently, the actual real-Q prime low maximum (including its selected exceptional character) and ordinary-square low maximum are now proved for all inputs, by a checked reduction to the already proved measure low theorem. Both use the same unchanged arithmetic construction and exact width. These deductions introduce no new deep input.

`Checkpoint_1082_RealIWSourceHighLow.md`

Checkpoint 1082: Complete real-Q source high-low proposition for both actual families

The complete printed real-Q high-low proposition is now assembled for actual prime and ordinary-square operators. One arithmetic construction retains the exact real-Q period bound, rational coverage, denominator bound and goodness. One selected Page datum is used for the prime low and high families. Both decomposition identities, both full all-input near-one low maxima, and the summed negative-quarter-power L2 high maximum above the exponential starting scale are checked. The universal parameter constant is enlarged once from C to C^2, and both low and high use the literal real-Q cutoff without rounding. The paper registry records p:orlicz-hilo as a complete conditional implication under the unchanged independent standard inputs. Five auxiliary source claims remain: four substantive incomplete claims and the completed sparse core awaiting its independently stated admissibility constant. Section9 remains untouched.

`Checkpoint_1083_RealIWMaximumNorms.md`

Checkpoint 1083: Literal real-Q maximal norms and reconciled seven-claim review

The literal countable maximum is now realized as an actual integer lp element for every all-input maximal bound at p<=2. A checked two-family norm theorem gives the sum of the real-Q prime and ordinary-square low maximum norms, with constant6 times the fixed complete-low constant times the literal real-Q cost. The final seven-claim review distinguishes the two newly completed conditional propositions, the complete sparse core awaiting its constant notation, and the four substantive partial claims. Earlier accepted source edits remain hashed and preserved; the new constant clarification is proposed separately. The remaining-work narrative is corrected to reflect the now complete sparse proof. No new deep input, source edit, or Section9 work is introduced.

Verification

All 1150 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4941-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3457 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1152 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The accepted Section8, admissibility, dyadic sparse-scale and retained-dilation edits are reconstructed in the selected manuscript, with original source copies and every label preserved. Only the accepted definition and dyadic auxiliary statement change inside numbered environments; no new full user upload is claimed. The seven remaining auxiliaries are being proved from their normal source hypotheses and

the explicitly recorded independent standard inputs. No own-paper conclusion is a new deep assumption. Section9 has not been started. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure, Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1084_AcceptedSparseRecursion.md`

Checkpoint 1084: Accepted current manuscript and complete generic sparse recursion

The complete current TeX upload is preserved exactly, and its accepted independent admissibility coefficient is verified. The generic dyadic sparse theorem now matches the source definition and is exported with its uniformly chosen admissibility threshold. It is recorded proved under its normal local hypothesis; no external sparse estimate is assumed. The selected working copy restores the previously approved factor-four dyadic sparse application and the preferred upper-cutoff wording, with the unchanged upload and exact replacement preserved. Four substantive auxiliaries remain partial. The user has newly authorized Section9 mapping and reductions.

<!-- checkpoint-verification -->

Verification

All 1151 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4942-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3459 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1153 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The current complete manuscript upload confirms the independent admissibility coefficient. The full generic sparse recursion is proved under its normal local hypothesis. The unchanged upload and a separate selected copy with the previously approved factor-four application restored are preserved. Four substantive auxiliaries remain partial. Section9 mapping and reductions are now authorized; later analytic and sieve inputs remain explicit. Theorem7.2 consumes the precise independent scalar quadratic Weyl approximation (including its unproved selection/reduction/phase bridge), general Tao construction, IW multiplier, major-arc/Shannon sampling, continuous/interpolation, signed-sequence and smooth multifrequency inputs, Page uniqueness and compatible raw prime-distribution data. All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumera-

tion proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure, Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1085_RationalFrequencyPeriod.md`

Checkpoint 1085: Rational common periods and the complete Section9 dependency map

Every numbered Section9 statement is now mapped: nine claims, their actual proof locations, forward dependencies on Sections10–11, the two CRT constructions and the final exceptional-set reduction. Mapping gives no proof credit and later own-paper conclusions are not new external inputs. Independently, an explicit common period for every denominator block is constructed by a factorial, and its rational-frequency logarithmic cost is proved at most 11(s+1). This is the arithmetic step needed for a sharper rational-frequency route; it does not assume the printed annular endpoint. The map flags the p2=z endpoint mismatch for a separate exact check.

All own ordinary and prime circle approximations, quantitative low/high comparisons, restricted estimates, parameter optimization and final source assembly are proved. Corollary7.6 adds no independent input. Theorem1.5(ii) additionally consumes only general strong Calderon transference, with actual prime enumeration proved. Corollary7.46 additionally uses general strong/modular Calderon transference and bounded-class polynomial convergence, including its still-unformalized published-theorem/cutoff/PNT/Abel/prime-power normalization bridges. Own unbounded Orlicz/L1 density convergence and identification of both limits are proved. These Prop-valued independent inputs are unproved theorem parameters, not new

Lean mathematical axioms. Earlier Theorems1.1/1.3 and Propositions4.19/6.21 retain their separate recorded inputs; older ordinary global/local stopping hypotheses are not consumed by this new ordinary IW route. Theorem1.5(i) uses only the precise general split-polynomial Weil, fixed-progression prime-frequency PNT, original LaVictoire weak-maximal-failure, Sawyer and Conze inputs. Their existence and exact published-to-Lean convention bridges remain unproved. The optional quoted general GK input has a precise interface and checked joint Poisson application, but is not consumed by badness. All current-paper arithmetic, moment, limit, frequency and persistence deductions are proved.

`Checkpoint_1086_RationalSmoothWeighted.md`

Checkpoint 1086: Rational-frequency annular deduction under the precise independent smooth input

The independent rational smooth multifrequency and circle-transference boundary is now stated precisely for arbitrary center sets and common periods. It contains no own annular or prime-square endpoint. From that explicit general input, the weighted smooth projection and actual annular maximum are freshly proved at large and every earlier starting scale for s>=2. The actual comparison error remains internally proved. The quoted rational-frequency theory and its transfer remain unformalized standard inputs; no Lean axiom is introduced and no full printed source claim is awarded completion at this intermediate stage.

This checkpoint passes a 4944-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3469 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1155 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The current complete manuscript upload confirms the independent admissibility coefficient. The full generic sparse recursion is proved under its normal local hypothesis. The unchanged upload and a separate selected copy with the previously approved factor-four application restored are preserved. Four substantive auxiliaries remain partial. Section9 mapping and reductions are now authorized; later analytic and sieve inputs remain explicit. The rational smooth multifrequency theorem together with circle transference is an explicit independent compound hypothesis; its existence is unproved. Its predicate contains no own-paper annular or truncated maximal conclusion. See docs/RATIONAL_MULTIFREQUENCY_BOUNDARY.md.

`Checkpoint_1087_RationalAnnularSourceMaximum.md`

Checkpoint 1087: Complete source annular multifrequency bound with first-power logarithmic loss

The full printed annular multifrequency lemma is now proved as a complete conditional implication with its first-power (1+s) bound, every dyadic source scale, all s>=0, scale1 and the small denominator cases. The precise independent rational smooth/transference input is explicit; the arithmetic period budget, own weighted projection, actual annular error and starting-scale arguments are checked. A matching rational-period proof passage is saved separately for the manuscript. The source lemma is not deduced by

dropping a logarithm from the older general smooth input. Its denominator-truncated corollary remains separately incomplete until all its own clauses are discharged.

Its predicate contains no own-paper annular or truncated maximal conclusion. See docs/RATIONAL_MULTIFREQUENCY_BOUNDARY.md.

`Checkpoint_1088_RationalAnnularTruncationMaximum.md`

Checkpoint 1088: Simultaneous real-denominator and time maximum with square loss

A single nonnegative integer L2 majorant now controls every dyadic time and every nonnegative real denominator cutoff simultaneously, with the printed square (1+s)^2 loss. The proof uses actual localized multiplier blocks and disjoint Bessel energies for large s, all 33 possible bounded denominator cutoffs for the small indices, and the three finite cutoffs needed at scale1. It invokes exactly the explicit rational smooth/transference and general smooth inputs already recorded at checkpoints1086–1087. No fixed-multiplier clause is credited yet; the full corollary remains partial until that clause is proved.

The current complete manuscript upload confirms the independent admissibility coefficient. The full generic sparse recursion is proved under its normal local hypothesis. The unchanged upload and a separate selected copy with the previously approved factor-four application restored are preserved. Two source statements remain partial: the original strong minor-arc clause and the broad standalone quantitative IW function classes. The full multifrequency lemma and denominator corollary, including measurable fixed symbols, are complete conditional implications. Section9 mapping is saved and its reductions are authorized; later circle-method and sieve conclusions remain internal proof obligations. The rational smooth multifrequency theorem together with circle transference is an explicit independent compound hypothesis; its existence is unproved. Its predicate contains no own-paper annular or truncated maximal conclusion. See docs/RATIONAL_MULTIFREQUENCY_BOUNDARY.md.

Checkpoint_1094_GoldbachFiniteRepresentations.md

Checkpoint 1094: Actual Goldbach representation sets and uniform prime-divisor exception bounds

Introduced the actual finite prime-plus-prime-square representation sets, primitive good set, residue-class admissible set, sifted set and explicit exception envelope indexed by prime divisors of n-1. Proved that a shared prime divisor of r-1 and n-1 must equal the represented square prime, bounds the entire exceptional set by omega(n-1), and gives the full uniform O_epsilon(N^epsilon) error for n-1<=N^2. The coprimality removal used in the upper reduction is proved as well. For n>12 in the source residue class, every representation has square prime>3 and r congruent11 modulo24. These arithmetic statements have no new external theorem inputs. The numbered sieve reductions are not promoted before their remaining set inclusions are proved.

`Checkpoint_1095_GoldbachFactorParity.md`

Checkpoint 1095: Multiplicity-sensitive modulo4 parity and the exactly-two factor count

Proved the exact modulo4 parity formula for lists whose factors are1 or3 modulo4, with bad factors retained with multiplicity. A product1 modulo4 has an even number of bad entries. The product lower bound shows that fewer than four entries can be at least z when the whole product is below z^4. If a bad factor exists, the bad list therefore has length exactly2, including repeated equal primes. These are unconditional arithmetic prerequisites for the actual Section9 truncation; no classical two-square criterion or Goldbach conclusion is assumed.

The rational smooth multifrequency theorem together with circle transference is an explicit independent compound hypothesis; its existence is unproved. Its predicate contains no own-paper annular or truncated maximal

conclusion. See docs/RATIONAL_MULTIFREQUENCY_BOUNDARY.md.

`Checkpoint_1096_GoldbachFullSiftedReduction.md`

Checkpoint 1096: Complete first Section9 sifted-count reduction with its explicit classical criterion

Completed the first actual Section9 lower-sifted counting reduction with exact finite error omega(n-1) and the complete uniform O_epsilon(N^epsilon) statement. The r-to-r-1 reindexing is proved injective and no own Goldbach conclusion is an input. The classical primitive two-square criterion is explicitly isolated as an independent unproved arithmetic hypothesis; no existence or unconditional proof is claimed. The statement ledger has12 proved,20 complete conditional,2 partial,1 quoted external and19 open claims. Later circle-method and sieve conclusions remain internal obligations.

Verification

All 1163 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4954-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3530 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1165 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The current complete manuscript upload confirms the independent admissibility coefficient. The full generic sparse recursion is proved under its normal local hypothesis. The unchanged upload and a separate selected copy with the previously approved factor-four application restored are preserved. Two source statements remain partial: the original strong minor-arc clause and the broad standalone quantitative IW function classes. The full multifrequency lemma and denominator corollary, including measurable fixed symbols, are complete conditional implications. Section9 mapping is saved and its reductions are authorized; later circle-method and sieve conclusions remain internal proof obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1097_GoldbachTwoLargePrimeFactors.md`

Checkpoint 1097: Exact two-large-prime factorization with a primitive-compatible remaining factor

Proved the complete integer factorization underlying the truncated sieve. For m congruent1 modulo4 with m<z^4, if a prime3 modulo4 divides m and every such prime is at least z, then m=u*p1*p2 with positive u, ordered primes z<=p2<=p1, and every prime divisor of u congruent1 modulo4. Prime factor lists retain multiplicity, so p1=p2 is included. Positivity, exact products, ordering and all remaining prime divisors are proved. This is an unconditional arithmetic theorem with no primitive two-square, sieve or current-paper analytic hypothesis.

`Checkpoint_1098_GoldbachTruncationSets.md`

Checkpoint 1098: Actual truncated bad set and both directions of the sieve classification

Defined the actual truncated bad representation set with ordered prime factors, the closed lower cutoff and all remaining factor conditions. Proved that every sifted nonprimitive representation outside the explicit prime-divisor envelope belongs to this set, using the exact multiplicity-sensitive factorization. Proved both converse inclusions: every truncated bad representation is sifted and is not primitive, while every good representation in the source n residue class is sifted. The only unformalized arithmetic input is the already explicit independent primitive two-square criterion. No circle-method or sieve asymptotic input is used.

Checkpoint_1100_GoldbachUpperFactorGeometry.md

Checkpoint 1100: Actual corrected upper-sieve sets and complete factor and cutoff geometry

Defined the corrected closed lower-cutoff L and L_n sets, the literal upper M_n(ell) representation set, the W sieve-prime predicate and actual quarter-power sifting level. Proved that every element of L is below N^2, so the finite indexing set loses no source element. Proved both factor geometry inequalities, the upper level bound by N^(1/2), the strict comparison with N^(1/alpha), and that a prime survives every smaller prime sieve. These are unconditional arithmetic/geometric facts. The eight-occurrence manuscript patch remains proposed and the selected source is unchanged; no full current-source upper-reduction credit is claimed.

Checkpoint_1101_GoldbachUpperSieveInclusion.md

Checkpoint 1101: Full corrected upper-sieve inclusion on the actual arithmetic sets

Proved the full actual set inclusion for the upper reduction with the proposed closed L cutoff. Every truncated bad representation outside the explicit prime-divisor exception envelope produces an element ell in the actual coprime L_n and belongs to its actual upper sifted set. The proof discharges factor geometry, finite bounds, q>3, the shifted representation identity, coprimality and survival of every sieve prime. This implication is purely arithmetic; it does not assume the primitive criterion or any analytic/sieve theorem. The source remains unchanged, and promotion of the printed upper statement awaits the documented cutoff correction and the finite count assembly.

`Checkpoint_1108_CorrectedPrimeSquareInput.md`

Checkpoint 1108: Complete corrected prime-square major and minor input

Corrected prime-square input: complete conditional implication at checkpoint1108

The current user upload adopts the complementary minor estimate R^(-1/4)(log N)^C. The selected copy also restores the matching approximation proof. The complete source lemma is exported as source_corrected_prime_square_input.

The same genuine optional primitive Page zero is selected for each N before Q, every modulus, phase, residue and real endpoint. Its conductor and zero region at the fixed exponential level are retained. The general progression input is uniform through exp(eta sqrt(log N)); eta and the error-decay constant c are independent positive constants. Taking their minimum supplies a fixed positive Q-range coefficient. Lean proves that q<=R^(11/10) is inside that distribution range and that the exact prefix error is absorbed by the inverse-fifth major error. The annular partial summation, prime-power/nonunit error, induced character and missing-character selector are all actual proved formulas.

The independent Ren and Ghosh inputs retain their full raw brackets. For every real frequency outside all reduced rational major arcs, the checked balanced approximation gives the complementary R^(-1/4)(log N)^d bound. Lean proves R^4<=N/2 and log N>=1 uniformly beyond one fixed threshold, for all allowed Q. No original stronger minor claim is assumed or asserted.

The remaining independent hypotheses are UniformPageProgressionInputs and UniformRenGhoshInputs. The first is a general fixed-level uniform prime-progression theorem, including its analytic Page-zero bridge; the second packages the already recorded general Ren/Ghosh estimates before Q. Their existence is unproved. Neither contains a quadratic major-arc conclusion, an approximation theorem or a paper-specific maximal estimate.

All source clauses of the corrected l:prime-square-input are matched. This closes the paper-specific deduction within the agreed conditional boundary, not the independent deep theorems. The broad quantitative IW proposition is the sole remaining incomplete standalone claim in Sections3–8.

`Checkpoint_1109_CyclicProductLpOperators.md`

Checkpoint 1109: Full real Lp cyclic product operator bound

Implemented the normalized cyclic Lp norm on families of actual Banach-space elements and proved its pointwise domination, translation and finite-sum properties. Proved the product operator bound for arbitrary full real Lp fibres, every finite exponent p>=1, arbitrary bounded real operator and every finite cyclic complex measure: the exact norm is at most its total variation times the real operator norm. The TV<=1 consequence has no Schwartz or L2-intersection restriction and adds no independent theorem hypothesis. This is the full-domain product estimate used in the broad IW multiplier application. The remaining deep IW and sampling theorems are still explicit external inputs, and the full proposition is not yet complete.

Verification

All 1176 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4967-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3578 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1178 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

The current complete manuscript upload confirms the independent admissibility coefficient. The full generic sparse recursion is proved under its normal local hypothesis. The unchanged upload and a separate selected copy with the previously approved factor-four application restored are preserved. Two earlier source statements remain partial: the original strong minor-arc clause and the broad standalone quantitative IW function classes. The full multifrequency lemma and denominator corollary, including measurable fixed symbols, are complete conditional implications. Section9 mapping is saved and its reductions are authorized; later circle-method and sieve conclusions remain internal proof obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1110_AEBoundedRealMultipliers.md`

Checkpoint 1110: Rough real Fourier symbols and full Lp realizations

Constructed arbitrary essentially bounded measurable real Fourier symbols, the actual bounded real-line L2 multipliers and their Fourier formulas without any continuity assumption. Proved exact scalar multiplication of symbols, operators and inverse Fourier kernels. Defined a full Lp Fourier realization as an actual bounded operator on the whole real Lp space agreeing with the given rough L2 multiplier on its genuine L2 intersection; this avoids mistaking an intersection norm for a full-domain operator. Its scalar-multiple realization is constructed with no deep input. These are foundations for the remaining broad IW clause, not an assertion of the deep theorem or a completion of the source proposition.

`Checkpoint_1111_FullSamplingFourierSupport.md`

Checkpoint 1111: Full Lp Fourier support and bandlimited sampling classes

Implemented Fourier support on the whole real Lp space using Mathlib's actual tempered-distribution Fourier transform, including p=infinity. Implemented the integer Fourier-support condition by its literal Schwartz test series and proved absolute convergence for every integer lp input, so no totalized divergent series can satisfy the condition vacuously. Implemented actual finite cyclic Fourier components and the full bandlimited real/cyclic Lp class, with continuous representatives retained for point sampling. Proved support enlargement and the equality between the full fibre-Lp norm and the previously normalized iterated real/cyclic norm. These classes do not impose Schwartz, integrability or L2 conditions. The general deep sampling theorems and source applications remain the next step.

Checkpoint_1112_FullAdelicIWApplication.md

Checkpoint 1112: Full rough-symbol adelic IW application and cyclic basis correction

Implemented the independent general full-domain adelic IW interface, with its rough-symbol limiting and finite-quotient/kernel bridges explicitly unproved. It quantifies over arbitrary good coprime data and arbitrary spatial cyclic families, not the source probability-measure specialization. Proved the exact rank-one kernel factorization and the full real-Q rough multiplier application. The output is an actual bounded operator on all integer lp inputs, with its literal finite-convolution Fourier kernel and operator norm <=C_rk times the actual full real Lp operator norm. The real/cyclic product estimate is discharged by the unconditional full-Lp module. Corrected the newly introduced sampling basis to denominators dividing P, with exact declared source hashes and required dependency rebuild; no source completion was awarded to the earlier incorrect class.

`Checkpoint_1114_QuantitativeIWSourceAssembly.md`

Checkpoint 1114: Complete all four quantitative IW clauses and close Sections 3–8 deductions

Full quantitative IW proposition: completed conditional deduction at checkpoint1114

The final theorem is proposition_quantitative_IW_full in `PrimeSquares/QuantitativeIWSourceAssembly.lean`. It chooses one arithmetic construction before the multiplier, p, complex measure, sampled input and target space. It is a complete implication under explicitly named independent general inputs, not an unconditional proof of Tao's theorems.

Source clause	Matched checked scope
(i), construction	Every real Q>=2^k, r>=2 and k>=4; exactly B=C^(k^2 Q^(1/(k-1/2))) and epsilon=(2^20 r B^(2r+8))^(-1); one positive integer P<=3^Q; every a/q modulo one for all integers a and all positive q<=Q, including unreduced fractions; all reduced denominators <=B; full (r,1/2)-goodness.

Source clause	Matched checked scope
(ii), multiplier	Arbitrary essentially bounded measurable real symbols supported almost everywhere in the closed narrow interval, arbitrary complex cyclic measures of total variation <=1, and every p in [p_r,2r]. The real norm is that of an operator on the whole real Lp space. The conclusion is an actual bounded operator on the whole integer lp space, with the literal projected inverse-Fourier convolution kernel and norm <=C_rk times the full real operator norm. Agreement on finite inputs determines this entire operator uniquely. No smoothness or L2-intersection restriction is substituted for the full operator.
(iii), major-arc sampling	The complete distributional Fourier-support lp class, both norm directions, the literal inverse-C_rk lower bound, unique interpolation and its exact sampled diagonal. The positive-exponent typeclass is proved from p>=p_r>1, not a new mathematical hypothesis. The normalized finite cyclic norm agrees with the earlier iterated real/cyclic norm.
(iv), Shannon sampling	Every finite-dimensional normed complex target, every extended exponent 1<=p<=infinity, every positive delta<=1/(100P), full real Lp fibres with distributional Fourier support, actual diagonal lp membership and both norm directions with one absolute sampling constant. No Hilbert, p<=2 or Schwartz restriction remains.

For point sampling, bandlimited functions are evaluated in their continuous representatives, as in the standard sampling convention. This does not impose Schwartz decay, integrability or L2 membership. An arbitrary modification of an Lp representative at individual points cannot define the sampling operator.

The real Fourier support is expressed using Mathlib's actual tempered-distribution Fourier transform. The integer support is expressed by its literal Schwartz-test Fourier series; absolute convergence is proved for every lp input. The finite cyclic Fourier basis is exactly the P-torsion rational set, not all denominators <=P. Its correction at1112 has exact source hashes and a complete dependency rebuild/audit; the final theorem explicitly proves every IW frequency belongs to the corrected basis.

The independent unproved inputs are RawTaoArcConstructionInput, RawFullAdelicIWInput, RawFullMajorArcSamplingInput and RawFullShannonInput. The last three general statements explicitly include their published-to-full-class/finite-quotient/kernel bridges; the general rough-symbol limiting argument is also not formalized. They quantify over arbitrary good coprime data or arbitrary narrow cyclic data, not the paper's chosen Q, probability measure, annular model, low/high estimate or maximal conclusion. The full real Lp product bound, coefficient specialization, exact construction applicability and source assembly are proved deductions. Checking their consuming implications does not prove these independent hypotheses true.

The earlier endpoint theorems retain their previously recorded, narrower assumptions. This broad standalone completion does not retroactively add the full-domain hypotheses to them. The Goldbach circle-method and sieve estimates remain open internal paper obligations.

Verification

All 1181 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4972-job dependency-aware build with remote project artifact reuse

disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3609 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1183 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1115_GoldbachFourierInversion.md`

Checkpoint 1115: Exact unweighted Goldbach Fourier inversion and full-cutoff removal

The Section10 Fourier identity is now proved for the literal unweighted prime sums. Prime cutoffs have arbitrary real endpoints, and membership is exactly primality together with m<=U. The progression cutoff retains ell*t<N^2 and t congruent to a modulo k. Neither a coprimality assumption nor a distribution theorem is needed for this identity.

The positive exponential convention is Mathlib's fourier j on the period-one circle with Haar mass one. Character orthogonality is proved from the existing Fourier basis; the product of the actual prime-square and progression polynomials is expanded before integration. The coefficient at n is exactly the complex embedding of the finite number of ordered prime pairs, including all real endpoint conventions. This is equation e:fourierinversion9, not an assumed Fourier identity.

For positive ell and n<N^2, goldbach_full_cutoffs_redundant proves that U=N, W=N^2 and ell*t<N^2 impose no additional restriction on the untruncated prime-pair count. All finiteness bounds are deduced from m^2+ell*t=n. The terminal goldbach_full_fourier_inversion therefore identifies the full representation count itself with the circle integral.

Eight new supporting theorems are unconditional. No analytic minor/major estimate, sieve bound, external theorem or paper endpoint is assumed or proved by this checkpoint. Lemma l:circmethod and the headline Goldbach theorem remain open; the exact Fourier bridge is a proved prerequisite. The user reports applying the complete approximation proof and the three earlier sparse/wording/strict-approximation edits. Work proceeds with the selected reconciled source; no new manuscript upload or verification of the user's editor is claimed.

`Checkpoint_1116_GoldbachMinorArcBessel.md`

Checkpoint 1116: Actual Goldbach minor-arc Bessel reduction and error assembly

The actual weighted progression sum is now defined with arbitrary complex coefficients and residues. The arithmetic-index set has precisely positive ell<L and positive k<V(ell), with strict arbitrary real cutoffs. Its membership equivalence is proved. The exact weighted Fourier identity and the full representation-count specialization are proved by finite linearity, not assumed.

The new goldbach_finite_fourier_bessel is a genuine finite Bessel inequality for arbitrary square-integrable circle functions, deduced from Mathlib's complete Fourier basis and the actual toLp representative. The set-restricted version applies to every measurable minor set and continuous prime/progression polynomials. It proves the literal bound sum_n |integral_minor P F e(-n theta)|^2 <= B^2 integral_circle |F|^2 from the pointwise bound |P|<=B on that set. Arbitrary finite integer output sets are allowed, so restriction to the paper's n<N^2 range costs nothing.

The theorem goldbach_actual_minor_bessel specializes this to the literal prime-square and weighted progression sums. A remaining bound on the actual progression energy is an INTERNAL proof obligation, as is the source's use of the independent raw prime exponential-sum estimate. Neither is renamed an external theorem. No logarithmic-saving hybrid estimate is claimed yet.

The exact major/minor decomposition of the weighted prime-pair count is proved for every measurable major set. The finite three-stage mean-square assembly proves the factor three in the source argument from the three successive INTERNAL error estimates. This assembles estimates once proved; it does not prove any of them by assumption. All eight supporting theorems use no new external deep input. The Bombieri–Vinogradov source lemma and the headline Goldbach theorem remain open.

`Checkpoint_1117_GoldbachProgressionEnergy.md`

Checkpoint 1117: Exact progression collision energy and off-diagonal prime geometry

The actual weighted progression energy has been opened by finite character orthogonality. The general goldbach_frequency_energy_identity proves the exact equality between the circle integral of the squared polynomial norm and the real part of the weighted sum over equal frequencies. Repeated frequencies are retained, so this is not an injectivity or disjointness assumption. Arbitrary complex coefficients are allowed.

For coefficients of norm at most one, goldbach_frequency_energy_le_collisions bounds the exact energy by the cardinality of the finite equal-frequency collision set. The actual progression events retain (ell,k,t), primality, the real W endpoint, ell*t<N^2 and the residue condition. The flat event polynomial is proved equal to the original nested progression polynomial. Thus goldbach_progression_energy_le_collisions is about the source's actual polynomial, not a replacement surrogate.

The composed goldbach_actual_minor_collision_bound has the literal natural-number output range n<N^2. It removes the free energy parameter from the earlier Bessel reduction and leaves only an explicit finite collision count and a pointwise prime-square minor bound. All coefficient and residue quantifiers remain arbitrary. Bounding that finite count by O(N^2 (log N)^6), and supplying the source uniform prime-square logarithmic bound, are still internal proof tasks; no such estimate is assumed to be a general external theorem.

The diagonal collision forces ell_1=ell_2. If t_1 and t_2 are distinct primes, the exact off-diagonal geometry ell_1=s*t_2 and ell_2=s*t_1 is proved, with a unique positive integer s whenever ell_1 is positive. This is the arithmetic starting point for the source dyadic Cauchy–Schwarz estimate.

All eight new supporting theorems are proved without a new independent deep input. Together, checkpoints1115–1117 prove the exact weighted Fourier bridge, measurable major/minor partition, actual Bessel inequality, explicit collision-energy reduction, diagonal/off-diagonal geometry and three-error assembly. The source hybrid logarithmic estimate, major approximation/completion, Bombieri–Vinogradov lemma, Section11 sieve/main-term/integral estimates and headline Goldbach theorem remain open. No manuscript replacement is newly required by this checkpoint.

Checkpoint_1118_GoldbachReciprocalLCM.md

Checkpoint 1118: Explicit reciprocal-lcm logarithmic bound for the Goldbach energy

The reciprocal-lcm estimate used in the source diagonal and congruence-fibre square bounds is now proved with an explicit constant. For every natural V, the sum over 1<=a,b<=V of 1/lcm(a,b) is at most H_V^3, hence at most (1+log V)^3. The V=0 and V=1 endpoints are included. The strict real-cutoff version is also proved for every real V>=1 and all positive integers a,b<V; this matches the varying source modulus cutoffs without rounding them upward inside the logarithm.

The proof is elementary and uses no new deep input. Each denominator pair injects into the triple (gcd(a,b),a/gcd(a,b),b/gcd(a,b)). The lcm is proved equal to the product of these three quantities. For positive bounded denominators, all three entries lie in [1,V]. Nonnegative summation and the proved injection therefore bound the reciprocal-lcm sum by the full product of three harmonic sums. Mathlib's existing elementary harmonic/logarithm comparison supplies the explicit logarithmic bound.

The new five supporting theorems do not assume the reciprocal-lcm estimate, a sieve theorem, a mean-square result or the paper's hybrid lemma. They are direct Lean proofs. The next source step is the uniform count of simultaneous congruences in an interval, followed by the dyadic Cauchy–Schwarz collision bound O(N^2(log N)^6). The source prime-square minor bound must then be derived in its exact parameter range from independently recorded raw exponential-sum inputs. The full hybrid estimate and both major estimates remain open, so no source-level completion credit is awarded to l:hybridminorarc or l:circmethod. Section11 and the headline Goldbach theorem remain open.

Checkpoints1115,1116,1117 and1118 are saved separately. They respectively establish exact unweighted Fourier inversion, the actual weighted Bessel/partition/error assembly, exact collision energy and prime geometry, and the reciprocal-lcm logarithmic estimate. No new manuscript replacement is required by these four checkpoints. The user's reported manuscript edits are recorded without claiming a new upload or a remote edit.

All 1185 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4976-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3638 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1187 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1119_GoldbachCongruenceCounting.md`

Checkpoint 1119: Uniform simultaneous-congruence interval counting

The simultaneous-congruence interval count is proved with exact constants. For any finite subset F of [A,A+T) whose members are pairwise congruent modulo q, card(F)<=T/q+1, first with natural division and then with literal real division. The proof chooses the least member only in the nonempty case and injects t into (t-min(F))/q. It therefore does not presume a compatible residue class or a solution. The empty case is separate; zero lengths and even the formal zero modulus are included.

The actual simultaneous congruence set retains both residue conditions. For any two of its members, Mathlib's Nat.mod_lcm proves congruence modulo lcm(k1,k2). Specialization yields card <=T/lcm(k1,k2)+1 in natural and real forms. Neither CRT existence, coprimality of the moduli/residues nor a prime-distribution theorem is assumed. These four supporting theorems supply the exact interval-counting ingredient in the source diagonal estimate and equation e:wellsquare9.

The reciprocal-lcm logarithmic bound was already proved at1118. Their combination into the actual squared multiplicity and progression-energy estimate is the next internal task. No source hybrid estimate, major estimate, sieve bound or headline theorem is newly declared complete. No manuscript replacement is required.

Checkpoint_1120_GoldbachCongruenceMultiplicity.md

Checkpoint 1120: Exact squared congruence-multiplicity estimate

The actual congruence multiplicity w(t), defined as the cardinality of moduli k satisfying t congruent to a(k) modulo k, is formalized. Its finite square is expanded exactly into the sum over pairs of moduli of the cardinality of their simultaneous-congruence set. No mean-square or counting estimate is assumed in this identity.

The interval count proved at1119 yields sum_{A<=t<A+T} w(t)^2 <= T sum_{k,j in K} 1/lcm(k,j)+card(K)^2. A proved subset version of the reciprocal-lcm bound therefore gives T H_M^3+card(K)^2 whenever K is any subset of [1,M]. This retains the local modulus count rather than replacing it by the global bound M^2, which would be too costly after summing over ell.

For every real V>=1, the literal strict source cutoff 0<k<V gives the exact bound T(1+log V)^3+V^2. This is a complete direct proof of the elementary squared-multiplicity estimate used in e:wellsquare9, with arbitrary residues and all natural interval endpoints. There is no coprimality, compatibility, prime-distribution or own-paper analytic assumption. The five new supporting theorems are unconditional arithmetic/finite-sum deductions. The full source progression-energy and hybrid minor estimates remain open.

A possible efficient route to the global energy uses grouping at each prime-product frequency and its number of distinct prime divisors. It will be checked explicitly before replacing the source dyadic bookkeeping in the formal proof. No manuscript edit is currently required.

`Checkpoint_1121_GoldbachPrimeFrequencyEnergy.md`

Checkpoint 1121: Prime-product frequency multiplicity and direct energy bound

A direct repeated-frequency energy principle is now proved. A finite exponential polynomial is regrouped exactly by its integer frequencies. Orthogonality and the already proved finite weighted square inequality give integral |sum c_i e(f_i theta)|^2 <= B sum |c_i|^2 whenever every frequency has at most B preimages. Repeated frequencies are counted, not silently treated as orthogonal.

For any finite set of pairs (ell,p) with positive ell and prime p, the fibre ell*p=m injects into the actual prime-divisor set of m by projection to p. Its cardinality is bounded by omega(m), independently of the coefficients. The elementary prime-product logarithmic budget already proved in the project yields omega(m)<=log X/log 2 whenever 0<m<=X. No PNT or distribution input is used.

Combining these statements gives a checked global energy bound for arbitrary complex coefficients indexed by positive ell and primes, with the factor log X/log 2 and the literal coefficient square sum. The seven new supporting theorems contain no new independent deep input. This alternative route can bypass the source dyadic off-diagonal bookkeeping once the arithmetic moduli are grouped correctly. That grouping and the final summation remain to be proved; no full progression-energy, hybrid or major-arc source claim is closed here. No manuscript replacement is required.

`Checkpoint_1122_GoldbachProgressionRows.md`

Checkpoint 1122: Exact prime-progression row grouping and energy reduction

The literal progression polynomial is now regrouped by its positive integer ell and its actual prime t. Each row retains exactly the moduli present in the original finite index set I. The membership equivalence for the row modulus set and the general row-sum identity are proved, so this regrouping does not duplicate or drop arithmetic indices.

The complex row coefficient is the sum of the original d(k,ell) over exactly those row moduli satisfying the source residue condition. Its norm is bounded by the actual congruence multiplicity when every coefficient has norm at most one. The full continuous circle polynomial is proved equal to the regrouped prime-product polynomial, with the original W cutoff and ell*t<N^2 restriction intact.

Applying the checked prime-frequency multiplicity bound yields an actual integral inequality: the energy is at most log(N^2)/log 2 times the sum over ell and 1<=t<=N^2/ell of the squared row congruence multiplicity. The extension from the original primes/W-cutoff to this finite interval is proved by an explicit injection and nonnegative summation. Only positivity of the source ell indices and the normal coefficient bound are needed. No prime-distribution, PNT or sieve theorem is assumed.

These five supporting theorems complete the exact bridge between the efficient frequency argument and the original progression polynomial. The remaining summation uses the row-square estimate proved at1120 and the printed local modulus-count bound. Its source-range verification is still to be supplied before claiming the full progression-energy estimate. No new manuscript replacement is required.

`Checkpoint_1123_GoldbachLogarithmicEnergy.md`

Checkpoint 1123: Global logarithmic prime-progression energy bound

The global row-square summation is now proved. For arbitrary positive ell in [1,X], arbitrary row modulus sets contained in [1,M], and the local numerical constraint card(K_ell)^2<=X/ell, the total squared congruence multiplicity over 1<=t<=X/ell is at most X(H_M^3+1)H_X. The proof uses the exact interval square bound, natural-to-real division inequality and a nonnegative harmonic sum. It does not use a dyadic mean-square assertion.

For the actual weighted prime-progression polynomial, this gives the explicit integral bound (log(N^2)/log 2) N^2(H_N^3+1)H_(N^2), provided the arithmetic indices have positive ell<=N^2, row moduli at most N and the local row-cardinality constraint. These are elementary numerical conditions to be derived from the printed source cutoff, not new deep or analytic hypotheses.

The same theorem is converted to the explicit stronger bound (8/log 2) N^2(1+log N)^5 for every natural N>=1. Prime-frequency multiplicity was proved at1121, actual row grouping at1122 and every finite-sum step is checked. The four new supporting theorems use no PNT, progression-distribution or sieve input.

Before claiming the source estimate e:remainingL2, the printed varying V_ell cutoff and L0 range must still be shown to imply these numerical conditions. The next checkpoint supplies that source bridge and the required sixth-power logarithmic form. The full hybrid minor lemma, both major estimates and the headline remain open. No manuscript replacement is required; a formal proof may use a stronger route than the printed bookkeeping.

`Checkpoint_1124_GoldbachSourceEnergy.md`

Checkpoint 1124: Complete the source logarithmic progression-energy estimate

The full source progression-energy bound e:remainingL2 is now proved from the printed numerical ranges. The exact terminal theorem goldbach_source_progression_energy_printed_range covers every natural N>=1 with log N>=1, every delta>0, every B>=0, every real L0<N^(2-delta), all varying real V_ell below sqrt(N^2/ell)(log N)^(-B), arbitrary real prime endpoint W, arbitrary residues and arbitrary complex coefficients of norm at most one.

Every elementary range condition of the efficient energy proof is discharged. The strict coefficient-index set gives positive ell and k; the L0 range implies ell<=N^2. For each nonempty row, V_ell>1. Monotonicity and the source cutoff give moduli at most N and card(K_ell)^2<=N^2/ell. Negative or too-small V_ell create empty rows and are not improperly squared. The logarithmic factor (log N)^(-B)<=1 and the real/Natural cutoff comparisons are proved explicitly.

The resulting literal circle integral is at most (256/log 2) N^2(log N)^6, with a constant independent of L0, V, residues, coefficients and W. The underlying general estimate at1123 is stronger, of order N^2(1+log N)^5. The proof groups arithmetic moduli before counting prime-product frequency multiplicities. It uses elementary prime-divisor logarithmic bounds and the checked congruence-square bound, and requires no PNT, Bombieri–Vinogradov, Siegel–Walfisz or new independent hypothesis.

The four new supporting theorems complete an unnumbered estimate inside the source hybrid-minor proof. The full l:hybridminorarc remains open until the actual prime-square logarithmic bound is supplied uniformly in its U range and combined with Bessel. The major-arc replacement/completion, combined l:circmethod, Section11 sieve/main-term/integral estimates and headline theorem remain open. No manuscript replacement is required by this alternative stronger formal proof.

`Checkpoint_1125_GoldbachHybridMinorReduction.md`

Checkpoint 1125: Hybrid minor-arc assembly with the prime-prefix obligation explicit

The full progression-energy estimate is now used in the literal minor-arc integral, with natural output range n<N^2 and the original weighted progression sums. For every measurable minor set, if the actual unweighted prime-square polynomial has pointwise norm at most C N(log N)^(-(A+6)/2), then its hybrid mean square is at most C^2(256/log 2) N^4(log N)^(-A). The exponent identity, all constants, source cutoff ranges and finite-output reindexing are proved explicitly. This reduction holds uniformly for every real prime endpoint U,W subject to that bound.

The displayed pointwise bound is still an INTERNAL analytic obligation. It is not a new independent deep input, not a Lean axiom and not a proof of the source l:hybridminorarc. The primary Ren Theorem1.1 was checked: it estimates annular von-Mangoldt sums, while the Goldbach polynomial uses unweighted prime prefixes. The actual partial-summation/prime-power/cutoff bridge remains to be proved rather than hidden in an external hypothesis. See docs/GOLDBACH_PRIME_INPUT_REVIEW.md.

These two supporting theorems discharge the entire mean-square assembly once that pointwise step is supplied. The general earlier prime exponential-sum input remains as previously recorded; no new independent hypothesis or manuscript replacement is introduced. Major-arc and sieve estimates remain open and can have their elementary arithmetic bridges prepared independently.

Checkpoint_1126_GoldbachMajorLCMReindexing.md

Checkpoint 1126: Major-arc lcm multiplicity and divisor-weighted error reindexing

The major-arc change from the modulus k to h=lcm(k,q) is now proved exactly. The fibre of k with lcm(k,q)=h is a subset of the actual divisors of h, hence contains at most tau(h) elements. No coprimality or guessed fibre multiplicity is imposed.

For every finite modulus set and nonnegative error function E, the sum of E(lcm(k,q)) is bounded by the sum of tau(h)E(h) over any interval covering all image moduli. The source tau(h)^2 version follows from an elementary natural-power inequality. The final theorem specializes this to complex progression errors bounded by R^2 E(lcm(k,q)), obtaining the exact weighted divisor-error sum used before the weighted Bombieri–Vinogradov input.

These five supporting theorems establish only the finite reindexing and multiplicity deductions. The actual progression error estimate, the weighted consequence of the general Bombieri–Vinogradov theorem and the full major approximation remain separate internal obligations. No new distribution theorem, own-paper estimate or mathematical axiom is assumed. The already completed progression energy and earlier source scopes are unchanged. No manuscript replacement is required.

Checkpoint_1127_GoldbachSieveResidues.md

Checkpoint 1127: Exact lower and upper sieve CRT residues and common product class

The literal lower and upper sieve residue choices in e:lowerresidue9 and e:upperresidue9 are now constructed in Lean using CRT and actual modular units. The helper for solving a*r=b modulo n constructs a bounded natural representative from a unit of ZMod n; it includes n=1. Congruence preserves the required coprimality by the actual gcd identity.

For every positive d coprime to6, a lower residue a<24d is constructed with a=11 mod24, a=1 modd and gcd(a,24d)=1. The source condition that all prime divisors of d exceed3 is separately proved to imply positivity and coprimality to6, so the source lower application is included; squarefreeness is not needed for this stronger arithmetic statement.

For ell=2v with gcd(v,6)=1 and positive d coprime to12ell, an upper residue a<12d is constructed with v*a=5 mod12, ell*a+1=0 modd and gcd(a,12d)=1. The second common residue b<12d is also constructed using only d, with b=10 mod12, b+1=0 modd and gcd(b,12d)=2. Every permitted upper residue satisfies ell*a=b mod12d. Thus the printed independence from ell and the exact gcd-two conclusion are proved, rather than inferred from examples.

All six supporting theorems are unconditional elementary arithmetic deductions. They do not assert the lower/upper sieve estimates, a sieve main-term lower bound, normalized integral positivity or the headline Goldbach theorem. The full progression-energy estimate is already proved at1124. The source hybrid minor still needs the actual weighted-annular to unweighted-prime-prefix bridge; major approximation/completion and the later analytic sieve work remain open. No new independent deep hypothesis or manuscript replacement is introduced.

All 3680 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1196 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

Checkpoint_1128_GoldbachFiniteAbel.md

Checkpoint 1128: Finite Abel summation and logarithmic unweighting

A finite Abel-summation norm inequality is now proved directly from Mathlib's exact summation-by-parts identity. For nonnegative decreasing real weights a_i and complex coefficients z_i whose actual partial sums have norm at most B, the weighted sum over range(n) has norm at most B*a_0. The proof includes n=0, the boundary term, the variation terms and their exact telescoping total. It is a proved inequality, not an additional summation-by-parts hypothesis.

The logarithmic removal weight is the actual function 1/log(max(2,n)). Its nonnegativity, monotonicity, initial value1/log2 and equality to1/log n at every n>=2 are all proved. Clipping at2 is only a finite-index convention: von-Mangoldt weights at0 and1 vanish. It prevents an invalid monotonicity assertion across log1=0.

These five supporting theorems supply the discrete logarithmic unweighting step. The next step identifies the unweighted Mangoldt sum with the actual prime sum up to the endpoint, apart from the already bounded higher prime-power contribution. The full Goldbach minor, major and sieve estimates are not newly claimed proved. No new independent deep input or manuscript replacement is introduced.

`Checkpoint_1129_GoldbachPrimeUnweighting.md`

Checkpoint 1129: Actual prime logarithmic unweighting and proper-prime-power error

The weighted-to-unweighted prime bridge is now proved for the literal Goldbach polynomial. Genuine Mangoldt partial sums and their logarithmically unweighted sums are defined with exact finite endpoints. Applying the finite Abel inequality at1128 gives norm at most B/log2 when all Mangoldt partial sums have norm at most B. The zero and one coefficients are handled explicitly.

For every prime p, logarithmic removal turns the actual von-Mangoldt coefficient into exactly one. The remainder is exactly the sum over nonprimes. Its norm is bounded using the already proved elementary

proper-prime-power mass estimate; no PNT or distribution input is added. For every M<=N with N>=1, the comparison error is at most (2/log2)sqrt(N)log N.

The real endpoint convention is proved through the actual natural floor, including endpoints at primes. The terminal theorem gives, for every 0<=U<=N and every circle frequency, |P_U| <= B/log2+(2/log2)sqrt(N)log N from a uniform bound B on the genuine Mangoldt partial sums up to N. The eight supporting theorems prove the complete logarithmic-unweighting and prime-power-removal step rather than assuming it.

It remains to construct the uniform Mangoldt partial-sum bound from the existing raw annular Ren/Ghosh input on the actual complementary arcs. The halving argument, arc rescaling and logarithmic parameter choice are the next internal steps. The full source hybrid minor estimate is not yet claimed complete. No new independent deep assumption or manuscript replacement is introduced.

`Checkpoint_1130_GoldbachHalvingPartials.md`

Checkpoint 1130: Exact Mangoldt halving reconstruction and uniform partial sums

The halving step is now proved by strong induction, with the exact integer floor at every scale. A bound on F(m)-F(floor(m/2)) above a real threshold H, together with a bound for the actual small partial sums, gives |F(m)|<=2 B m+E. The proof includes zero and odd scales and uses 2 floor(m/2)<=m; no unproved dyadic reconstruction is inserted.

For the genuine Mangoldt exponential sums, the half-scale identity is proved from the exact finite intervals. The positive Fourier phase is identified with the existing Ren convention. Its annular difference

has norm exactly m times the actual normalized annular symbol. A crude small-scale bound |S_m|<=m log N is proved directly from the elementary pointwise von-Mangoldt/logarithm inequality, without PNT or a prime-counting hypothesis.

The terminal theorem assembles the uniform bound |S_m|<=2 B N+H log N for all m<=N from a common annular symbol bound B above H. These seven supporting theorems discharge the discrete reconstruction and all finite cutoff conventions. The common annular estimate will next be supplied by the existing raw Ren/Ghosh inputs using explicit rescaled complementary arcs. No new independent deep hypothesis or manuscript replacement is introduced.

`Checkpoint_1131_GoldbachMinorArcGeometry.md`

Checkpoint 1131: Exact minor-arc region and rescaling between annular scales

The source minor-arc region is now an explicit measurable subset of the circle: the complement of the closed major arcs of uniform radius R/N^2 about reduced rational centres with denominator at most R. Its definition using all rational lifts is proved equivalent to the existing finite source-centre definition. Circle distance is bounded by the distance between any real lifts. These facts give a proved scale transfer: membership in the source minor arcs at scale N implies the annular Ren/Ghosh exclusion at every scale $1 \le m \le N$ with parameter $R(m/N)^2$. The denominator-dependent annular exclusion and all integer lifts are covered explicitly. No prime estimate is introduced as an independent hypothesis.

`Checkpoint_1132_GoldbachUniformAnnularMinor.md`

Checkpoint 1132: Actual prime partial sums from raw annular Ren-Ghosh inputs

The common annular bound at all relevant smaller scales is derived from the already recorded raw Ren/Ghosh input. It uses the proved rescaling of the actual source minor arcs. The assumptions are explicit elementary inequalities on a common cutoff H and radius R; in particular $R^4 \le H/2$ and $1 \le R(H/N)^2$. The strong-induction halving identity reconstructs all von Mangoldt partial sums. Finite Abel summation then removes the logarithmic prime weight, and the proved proper-prime-power mass bound accounts for the nonprime terms. The result bounds the actual unweighted prime-square polynomial for every real $0 \le U \le N$. The only independent analytic assumption remains UniformRenGhoshInputs. The paper's own pointwise prime estimate is not assumed.

`Checkpoint_1133_GoldbachMinorLogParameters.md`

Checkpoint 1133: Explicit logarithmic parameters for the actual minor-arc prime saving

The logarithmic parameters are explicit. For target saving t > 0, set K=t+2, H=N(log N)^(-K), and take any C ≥ 6t+4d+8, where d is the logarithmic exponent in the existing raw Ren/Ghosh input. The rescaled annular radius is exactly (log N)^(C-2K). Its quarter-power saving absorbs both d and the target t. The small-scale term H log N equals N(log N)^(-t-1). Once the elementary eventual scale and square-root budgets hold, the actual prime polynomial has the uniform bound Z N(log N)^(-t), where Z=(2P+3)/log 2 and P is the sum of the proved Ren/Ghosh constants. Every C above the threshold is allowed. No own endpoint estimate is an assumption.

Checkpoint_1134_GoldbachMinorEventualCutoffs.md

Checkpoint 1134: Eventual cutoff and proper-prime-power budgets without extra inputs

All numeric assumptions needed by the prime minor-arc estimate are now proved eventually. The proof uses the formal logarithm-versus-positive-power limit with explicit constants. For every fixed target t and radius exponent C, a natural threshold $N_0 \geq 4$ works simultaneously for log N ≥ 1, H=N(log N)^(-(t+2)) ≥ max(4,startingScale,exp 1), (log N)^(4C) ≤ H/2, and sqrt(N) log N ≤ N(log N)^(-t). The threshold is independent of the real prime cutoff U, the circle frequency, the progression cutoff W, the coefficient family, and the residue classes. This discharges the finite-scale and proper-prime-power budgets without introducing a new analytic hypothesis.

Checkpoint_1135_GoldbachPrimeMinorUniform.md

Checkpoint 1135: Uniform actual prime minor bound and the printed large-cutoff estimate

For each t > 0 and every C ≥ 6t+4d+8, one natural $N_0 \geq 4$ now gives the actual uniform circle estimate |P_U(θ)| ≤ Z N(log N)^(-t) on the literal source minor arcs, simultaneously for all real 0 ≤ U ≤ N. Quotient representatives are handled explicitly, so this is a theorem about the circle polynomial, not a chosen real lift. The threshold is independent of U, W, θ and all progression/coefficient data. Taking t=3s+1 also proves the stronger displayed source estimate |P_U| ≤ Z (U/log U)(log N)^(-s) whenever 2 ≤ U ≤ N and U ≥ N(log N)^(-2s). Thus the printed large-cutoff prime estimate is covered as well as the bound needed for Bessel. Only the existing raw UniformRenGhoshInputs is assumed.

`Checkpoint_1136_GoldbachHybridMinorComplete.md`

Checkpoint 1136: Complete source hybrid minor-arc estimate from raw Ren-Ghosh inputs

The full source hybrid minor-arc lemma l:hybridminorarc is now a complete implication under the existing independent raw UniformRenGhoshInputs. For every A>0, take C_0=3A+4d+26. Every real C≥C_0 is allowed; one N_0≥4 then works uniformly in all printed coefficient, residue and cutoff data. The actual mean square over n<N^2 is at most K N^4(log N)^(-A), with K=Z^2(256/log 2) and Z=(2P+3)/log 2. The theorem covers every B≥0, δ>0, the strict printed L_0 and V_ell ranges, all coefficients of norm at most1, all residue families, every real 0≤U≤N and arbitrary real W. Thus it includes the source ranges 2≤U≤N and 2≤W≤N^2. The minor set is the exact measurable complement of the closed source arcs of uniform radius (log N)^C/N^2. All Abel, proper-prime-power, halving, scale-transfer, logarithmic-parameter, progression-energy and Bessel steps are proved. No own-paper endpoint is assumed. This closes only the hybrid minor lemma; the full circle-method approximation and Section11 endpoints remain open.

`Checkpoint_1137_GoldbachMajorStrictEndpoint.md`

Checkpoint 1137: Exact strict progression cutoff and the possible prime endpoint

The strict source cutoff ell*t<N^2 is retained. When W≤N^2/ell, the actual progression cutoff equals the ordinary prime progression cutoff with the possible equality ell*t=N^2 removed. There is at most one such prime, and the corresponding actual complex exponential-sum difference has norm at most1. Replacing W by min(W,N^2/ell) is proved to leave the strict source cutoff unchanged. This corrects the boundary bookkeeping required before partial summation: the manuscript sentence saying the strict condition is automatic under a non-strict bound is false at equality. No main theorem change is inferred; the finite endpoint term is explicit and still has to be included in the eventual major-arc bound. The source archive and selected manuscript are preserved unchanged.

Verification

All 1205 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 4996-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3735 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1207 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypoth-

esis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1139_GoldbachCountingPartialSummation.md`

Checkpoint 1139: Quantitative partial summation from actual prime-count discrepancies

Quantitative partial summation is proved for actual finite counting sums and a differentiable model with zero lower value at2. The prime at2 remains in the finite sum; no artificial lower-bound convention is assumed. The identity is derived from Mathlib Abel summation and integration by parts, with all integrability obligations proved. A unit-norm phase with derivative bounded by D transports a uniform counting discrepancy B to error at most B(1+D(U-2)). Specializing to the actual prime progression coefficient and actual Li/phi model gives the needed unweighted prime exponential-sum implication. This is an internal proved conversion, not an external weighted prime estimate.

`Checkpoint_1140_GoldbachPrimePhaseErrors.md`

Checkpoint 1140: Actual linear and quadratic major-arc errors from prime counts

The actual positive quadratic and linear logarithmic integrals are defined. The positive linear oscillation has its exact real derivative, continuity and unit norm; the existing quadratic derivative is reused with the explicit sign reversal. The actual progression-density integrals equal the logarithmic integrals divided by phi(k), with the factor pulled through the Bochner integral rigorously. The proved counting partial-summation identity now gives quadratic error B(1+4*pi*|gamma|*U^2) and linear error B(1+2*pi*|beta|*U). These are deductions from ordinary prime-count discrepancies for the literal finite sums. No SW/BV theorem, own weighted estimate or model equality is assumed.

`Checkpoint_1141_GoldbachSquareMajorCounts.md`

Checkpoint 1141: Exact square major-arc model and its prime-count discrepancy bound

The actual positive prime-square polynomial is identified with the previously proved finite square symbol under the exact phase reflection. Actual prime progression cutoffs agree with residue fibres modulo q. The exceptional nonunit primes are bounded unconditionally by q. The existing finite Gauss assembly then gives the literal source square major-arc model s(-a,q) I_U(gamma), with error at most q+phi(q) B(1+4*pi*|gamma|*U²) when the ordinary reduced prime-count discrepancies up to U are at most B. Both the sign and the totient factor are proved, and the nonunit remainder is retained explicitly. A raw Siegel–Walfisz theorem will supply the ordinary counting discrepancy; the own square approximation is not an external input.

Checkpoint_1142_GoldbachMajorLCMQFibres.md

Checkpoint 1142: Fixed-denominator lcm fibres and reduction to ordinary BV

For every fixed major denominator q, a fibre of k↦lcm(k,q)=h has cardinality at most q. The injection is k↦h/k; its values lie in1..q and determine k exactly. Consequently the sum of unweighted distribution errors over k is at most q times the ordinary sum over moduli h. If q≤R and each progression error is at most R^2 times the error for its lcm modulus, the total is at most R^3 times the ordinary unweighted distribution-error sum. This proves an efficient route from classical unweighted BV to the actual progression approximation: all losses depending on q are powers of R=(log N)^C and can be absorbed in the requested logarithmic saving. No divisor-weighted BV theorem or divisor-moment input is needed for this route.

Checkpoint_1143_GoldbachMajorCompatibleResidues.md

Checkpoint 1143: Compatible lcm unit residues and generalized CRT

The reduced residue classes modulo lcm(k,q) compatible with the prescribed residue modulo k are actual finite sets of natural representatives. Their reduction modulo q is injective, so their cardinality is at most q. The generalized CRT constructs every class compatible modulo gcd(k,q), with exact representative bounds and both unit conditions. The converse compatibility and unit properties are proved. These facts retain shared prime factors of k and q; no coprime-moduli simplification is imposed.

Checkpoint_1144_GoldbachMajorUpsilonIdentity.md

Checkpoint 1144: Exact Upsilon normalization from compatible lcm residues

The compatible lcm residues are proved to map bijectively onto the actual unit residues modulo q satisfying the gcd compatibility condition. The map preserves every additive character. The finite character sum divided by phi(lcm(k,q)) is therefore exactly Upsilon(q,k,a,-alpha)/phi(k), with the source negative argument and both totient factors. Shared-prime cases are included through generalized CRT, not excluded. No analytic distribution hypothesis is used in this arithmetic identity.

`Checkpoint_1145_GoldbachRawPrimeDistribution.md`

Checkpoint 1145: Precise ordinary prime-count SW-BV inputs and elementary budgets

Precise independent general SW and BV interfaces are recorded only for actual ordinary unweighted prime counts relative to the actual logarithmic integral divided by phi(h). Their complex discrepancy is proved equal to the usual real absolute error. SW is uniform in the reduced residue, all endpoints up to N and every fixed logarithmic modulus range. BV has the classical endpoint maximum and an unweighted modulus sum up to sqrt(X)(log X)^(-L), with an honest error majorant for the actual counts. Neither interface mentions a quadratic phase, the paper's coefficient family or a circle-method conclusion. The external theorems remain unproved propositions, not Lean axioms. The source square approximation is reduced numerically to R+(1+4*pi)R² times its ordinary count discrepancy; the necessary logarithmic power identity and eventual radius-error absorption are proved. The full SW square application is the next internal deduction. The fixed-q lcm bound permits ordinary BV directly, with no extra divisor-weighted distribution input.

`Checkpoint_1146_GoldbachSquareMajorSW.md`

Checkpoint 1146: Full uniform SW square major-arc approximation from ordinary prime counts

The full actual square major approximation is now proved from the ordinary unweighted SW interface. For every t>0 and C≥0, a positive constant and one natural threshold work simultaneously for all positive q≤(log N)^C, all integer numerators, every real2≤U≤N and every |gamma|≤(log N)^C/N². The model is exactly s(-a,q) I_U(gamma), with the actual logarithmic integral. The error is at most K N(log N)^(-t). Every prime cutoff, rational sign, residue normalization, nonunit term and eventual power absorption is proved. No large-U-only restriction or weighted square approximation is an assumption. The classical ordinary SW theorem remains the explicit independent unproved input.

Checkpoint_1148_GoldbachLinearMajorCounts.md

Checkpoint 1148: Actual linear Upsilon model with every nonunit and endpoint error

The actual good linear prime sum is approximated by the exact source Upsilon coefficient times the logarithmic integral, with error at most q B(1+2*pi*|ell*gamma| W) from ordinary prime-count discrepancies for the lcm modulus. All compatible classes are present. Primes nonunit modulo lcm(k,q) are proved to divide q using the source coprime residue condition, and their total norm is at most q. The strict source endpoint contributes at most1. Thus the actual full progression polynomial has the source model with the explicit error1+q+q B(1+2*pi*|ell*gamma| W). No omitted exceptional prime or equality endpoint is hidden in a distribution assumption.

Checkpoint_1149_GoldbachLinearSourceIntegral.md

Checkpoint 1149: Exact strict Euclidean source integral and numeric major-arc error

The actual strict Euclidean source integral J_{ell,W} is defined using2≤v≤W and ell*v<N². Its domain is proved almost everywhere equal to (2,min(W,N²/ell)], so the integral equals the actual closed logarithmic integral at the clamped endpoint. Both the prime cutoff and the integral are therefore matched exactly under clamping, including equality cases. The actual full linear progression model is proved for every real W≥2 whenever N²/ell≥2. On a source major arc its error is at most1+q+(1+2*pi)R² B. Every domain and boundary correction is retained explicitly; the strict source condition is never replaced by an automatic non-strict condition.

Checkpoint 1150: Actual ordinary-BV row approximation with independent prime cutoffs

The actual source linear major model and error are explicit functions. The sum of error norms over an arbitrary finite row of positive moduli is bounded by (1+q)card(K)+(1+2*pi)R³ times the ordinary unweighted modulus-distribution error sum. Each progression may have its own real cutoff W_k≥2 and its own coprime residue. Applying RawPrimeBombieriVinogradovInput gives one level, constant and starting scale chosen before q, all residue families and cutoffs. The remaining terms1+q are exactly the retained nonunit/strict-endpoint contribution, not an unproved distribution assumption. This completes the genuine BV row conversion. Matching the paper's source level and summing over ell are the next internal steps.

Verification

All 1217 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5008-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before

reuse; new/changed modules and the root are compiled. All 3788 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1219 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1151_GoldbachBVSourceParameters.md`

Checkpoint 1151: Printed source ranges imply the ordinary BV level uniformly

The source arithmetic scale X_ell=N²/ell is proved to satisfy N^delta<X_ell≤N² under the printed strict ell range. The exact logarithmic comparisons delta log N≤log X_ell≤2 log N follow. Taking B≥C+L+1 and log N≥2^L puts V_ell R below the classical BV level sqrt(X_ell)(log X_ell)^(-L). The logarithmic saving at X_ell is converted to the saving at N with explicit factor delta^(-T). One natural threshold, independent of ell and the major denominator, is proved to ensure the required starting-scale and logarithmic inequalities. The lcm moduli then lie in the BV range. No source range is strengthened silently.

classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

Checkpoint_1152_GoldbachMajorSourceCounts.md

Checkpoint 1152: Actual source row sums and coefficient-family cardinality bounds

The actual active row set lies in1..N^2, its reciprocal sum is bounded by the harmonic number, and the sum of X_ell=N^2/ell is at most3N^2 log N. The number of active rows is bounded by max(L0,0), including empty and negative-cutoff cases. Exact row regrouping and Cauchy–Schwarz give card(I)^2≤3N^2 max(L0,0) log N from the printed square-root row cutoffs. These are proved finite-count bounds for the actual coefficient family; they will absorb every retained prime endpoint/nonunit term with the source N^(-delta) margin.

Checkpoint_1153_GoldbachMajorFiniteErrorAbsorption.md

Checkpoint 1153: Uniform absorption of all strict-endpoint and nonunit prime errors

The actual coefficient-family cardinality satisfies card(I)^2≤3N^(4-delta) log N under the printed strict L0 and logarithmic V_ell ranges. An explicit logarithm-versus-power budget is proved eventually. Combining the square bounds proves2(log N)^C card(I)≤N^2(log N)^(-t) for every fixed desired saving, with one threshold independent of all cutoffs and residue data. Thus every retained1+q term from a strict prime endpoint or a prime dividing q is absorbed uniformly, since1+q≤2R. This closes the previously identified finite-boundary issue without changing the stated approximation theorem.

`Checkpoint_1154_GoldbachLinearMajorBV.md`

Checkpoint 1154: Full actual source BV progression approximation uniformly in every cutoff

The full actual source progression approximation is proved from ordinary unweighted BV. For every desired saving t>0, every C≥0 and every delta>0, one B0≥0, positive constant and natural threshold work uniformly for every B≥B0, every printed strict L0 and V_ell range, every source major denominator/numerator/offset, all coprime residue families and all independently chosen real progression cutoffs W_i≥2. The sum of the actual source error norms is at most K N²(log N)^(-t). The models use the exact Upsilon factor and exact strict Euclidean J integral. The fixed-q lcm fibre bound, source BV level, logarithmic conversion, ell-scale sum and every endpoint/nonunit error are all discharged. Only RawPrimeBombieriVinogradovInput remains independent and unproved. This proves the source pointwise linear estimate, not yet its full circle mean-square assembly.

`Checkpoint_1155_GoldbachMajorArcGeometry.md`

Checkpoint 1155: Exact source major-arc geometry measure and disjointness

The major set is exactly the complement of the already formalized source minor set and equals the finite union of the source closed balls of uniform radius R/N^2. Its measurability, rational-centre cardinality at most$4R^2$ and normalized Haar measure at most$8R^3/N^2$ are proved. Exact real lifts turn circle ball membership into the integer-shift inequalities used in the earlier rational separation theorem. Consequently the source major balls are pairwise disjoint once$2R^3<N^2$. A single eventual threshold proves this separation and radius<1/2 for R=(log N)^C and every fixed C≥0. No arc, wrap-around or measure convention is assumed.

`Checkpoint_1156_GoldbachMajorModelRegularity.md`

Checkpoint 1156: Measurable source coordinates and actual Euclidean model bounds

A canonical measurable local circle coordinate is constructed at every rational centre. Its real absolute value is exactly the circle distance, it lies in[-1/2,1/2), and it reconstructs the original circle point. The actual square and linear logarithmic integrals are strongly measurable in frequency, by the Bochner parameter-integral theorem. The strict source linear integral inherits this regularity through its proved clamping identity. Their uniform norm bounds are proved from the actual1/log weight: |I_U|≤U/log2 and |J_ell,W|≤W/log2 in the required range. No abstract Euclidean model, measurable representative, or size estimate is assumed.

Checkpoint_1157_GoldbachCircleMajorModels.md

Checkpoint 1157: Constructed measurable source major-arc models with all-Lp regularity

The source major-arc models are now actual measurable functions on the circle, constructed as finite indicators of the exact source major balls times the genuine local-coordinate integrals. A general localization theorem proves their precise source value on each arc using the checked pairwise disjointness. Uniform Euclidean bounds prove membership in every Lp, including infinity; this is not a measurable-model hypothesis. The square model has the exact Gauss coefficient and norm at most N/log2 on the major set. The progression model has the exact Upsilon/phi coefficient and strict source J integral. All quotient representatives, boundary values, and finite model sums are explicit.

Checkpoint_1158_GoldbachCircleMajorEstimates.md

Checkpoint 1158: Full SW-BV bounds for the constructed exact circle models

The completed actual real-frequency SW and BV estimates are transported to the constructed source circle models. At every point of the exact source major set, the selected local coordinate reconstructs that point with its canonical reduced numerator and denominator. SW therefore bounds the actual square polynomial minus its circle model uniformly. BV bounds the sum of the actual progression-minus-model

norms over the entire source coefficient family, with independent real prime cutoffs and all source ranges. All constants and thresholds precede the arithmetic/cutoff data, and the active ell scales are proved at least2 for model integrability. No arc matching, choice of rational approximant, or global model comparison remains assumed.

`Checkpoint_1159_GoldbachMajorBesselAssembly.md`

Checkpoint 1159: Restricted Bessel assembly for the two major-arc replacements

The restricted Bessel inequality is proved for arbitrary measurable circle functions in L^2, by applying the finite Fourier Bessel inequality to their indicators. A uniform major-arc error costs the normalized measure of the major arcs. A bounded measurable multiplier costs its squared bound times the full progression energy.

For the actual two-factor replacement, the exact identity $PF-QG=Q(F-G)+(P-Q)F$ is integrated and the two squared errors are bounded by $2(BQ^2\ BE^2\ \mu(\text{major})+BP^2\ E)$. All integrability and finite Fourier summations are proved. No endpoint approximation is assumed. The independent ordinary SW and BV inputs are not used by this general assembly theorem.

`Checkpoint_1160_GoldbachMajorWeightedAssembly.md`

Checkpoint 1160: Weighted source coefficient identity and exact major-arc budget

The weighted progression major model is constructed from the actual source models and proved to lie in every Lp space on the circle. For coefficients of norm at most one, its difference from the actual weighted prime polynomial is bounded by the sum of the individual progression error norms.

The source sum of weighted major-arc Fourier integrals is proved exactly equal to the Fourier integral of the two weighted factors. All finite sum exchanges and integrability conditions are supplied. The final numerical identity combines the major-arc measure bound$8R^3/N^2$ with the SW loss N(log N)^(-(A+6)/2), the BV loss N^2(log N)^(-(A+3C)/2), and the proved progression-energy bound(256/log2)N^2(log N)^6. It yields an explicit constant times N^4(log N)^(-A). No own-paper endpoint is an input.

`Checkpoint_1161_GoldbachMajorApproximationComplete.md`

Checkpoint 1161: Complete source major-arc approximation under ordinary SW and BV

The full source major-arc approximation, stable label l:majorapproximation9, is now a complete Lean implication under only RawPrimeSiegelWalfiszInput and RawPrimeBombieriVinogradovInput. These independent hypotheses concern ordinary unweighted prime progression counts; neither contains an oscillatory model, the paper coefficient family or its endpoint conclusion. Their analytic proofs remain external.

For every A>0, C≥0 and delta>0, the theorem selects B0, a positive error constant and a sufficiently large integer scale before all source data. It covers every B≥B0, every strict printed L0 and V range, every reduced progression residue and bounded complex coefficient, every real2≤U≤N and every realW≥2. In particular it covers the paper's W≤N^2 range. The sum over all natural n<N^2 is exactly the source weighted sum of model-replacement integrals on the actual circle major arcs, bounded by K N^4(log N)^(-A).

The actual Fourier signs, rational centres, normalized measure, strict prime cutoff, nonunit primes, Upsilon coefficient, genuine Euclidean integrals and measurable circle models are all supplied. SW uses exponent(A+6)/2; BV uses(A+3C)/2. Restricted Bessel, the measure bound8R^3/N^2 and the previously proved progression-energy bound give the explicit final constant2(8 KE^2/(log2)²+KP^2·256/log2).

A small proof correction is required: W≤N^2/ell does not make ell*t<N^2 automatic at equality. The endpoint and primes dividingq contribute at most1+q to each individual error. All these finite errors are proved absorbed uniformly. The separate replacement files retain the lemma statement and equation labels and give the checked unweighted fixed-q fibre route. The selected manuscript is unchanged.

This closes one paper-level claim after review of its exact source statement and quantifiers. The ledger is now13 proved,26 complete conditional implications,1 quoted external theorem and14 open. The full circle-method approximation l:circmethod still requires completion/arithmetic evaluation and the smooth Euclidean-cutoff stage. Section11 and the headline Goldbach theorem remain open.

Verification

All 1228 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5019-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3846 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1230 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional

Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

Checkpoint_1162_GoldbachArithmeticEuler.md

Checkpoint 1162: Absolute convergence and exact source arithmetic Euler factor

The actual source R-smooth coefficient series is defined with the inclusive prime cutoff p≤R. Its finite support is proved inside the explicit divisor set from the earlier arbitrary-multiplier Euler theorem. Absolute summability is proved for the norm series, with no analytic distribution input.

The complete sum is identified exactly with the source two-adic factor times the product of the actual unit-pair solution counts for2<p≤R. The floor conversion includes primes equal to R. An exact finite split at every real denominator cutoff Y is supplied. This closes the algebraic identity and convergence clauses of l:arithmeticcoefficients9; its quantitative bounds and the full completion/smoothing estimates remain open. The already completed SW/BV major replacement and hybrid minor scopes are unchanged.

Checkpoint_1163_GoldbachEuclideanDecay.md

Checkpoint 1163: Genuine reciprocal-log Euclidean integral decay

The actual reciprocal-log weight is proved antitone on every source interval. Mathlib's general vector-valued second mean value theorem, proved in the pinned dependency, transfers the existing unweighted quadratic oscillatory bound to the genuine source integral: norm I_U(gamma)≤(2 quadraticIntegralConstant/log2)/sqrt(abs gamma).

The actual linear exponential primitive is differentiated and integrated exactly. This gives norm of its interval integral≤1/(pi abs beta), then norm J_U(beta)≤1/(pi log2 abs beta). The strict-domain source integral is identified with its clamped endpoint and satisfies norm J_ell,W(gamma)≤1/(pi log2 ell abs gamma). No van der Corput or Fourier-decay assertion is assumed externally. The results are uniform for every real cutoff in the printed range. The quantitative arithmetic bounds, smoothing assembly and full l:circmethod remain open.

`Checkpoint_1164_GoldbachTotientHarmonic.md`

Checkpoint 1164: Unconditional reciprocal-totient harmonic bounds

The reciprocal totient is bounded by the earlier actual conductor-correlation product divided by n. Its previously proved weighted harmonic estimate gives sum_{n≤D}1/phi(n)≤exp(2) H_D without an external average-totient input.

For every positive divisor d, the sum restricted to d|n is bounded by exp(2) H_D/phi(d). The proof uses the injective quotient n↦n/d and the proved supermultiplicativity phi(d)phi(n/d)≤phi(n). The actual gcd is expanded exactly as the sum of phi(d) over common divisors. These are unconditional arithmetic prerequisites for the source family harmonic estimate; the quantitative coefficient bounds and full major completion remain open.

`Checkpoint_1165_GoldbachArithmeticHarmonic.md`

Checkpoint 1165: Complete source weighted arithmetic harmonic estimate

The complete source weighted gcd/totient harmonic estimate e:harmonicsum9 is proved with explicit constant9 exp(2) and divisor exponent2. It holds for the actual strict coefficient family in every printed $B\geq 0$ and $L\leq N^2$ range, including empty rows and negative cutoffs.

The proof expands gcd(q,n) exactly through common-divisor totients. Reciprocal multiples give sum $\gcd(q,n)/n\leq\tau(q)$ H_D. The previous totient-multiples theorem gives sum $\gcd(q,n)/\varphi(n)\leq\tau(q)$ exp(2) H_D. The proved divisor relation $\gcd(q,ab)\mid\gcd(q,a)\gcd(q,b)$ separates the double sum. Extending the actual family to the N^2 rectangle and using $H_{N^2}\leq 3\log N$ gives9 exp(2) $\tau(q)^2(\log N)^2$. No sieve, average-totient or other independent input is assumed. The arithmetic coefficient decay and full major completion remain internal open obligations.

Checkpoint_1166_GoldbachArithmeticPrime.md

Checkpoint 1166: Exact coefficient identities and odd-prime gcd decay

Three exact identities are proved for the genuine arbitrary-multiplier coefficient: when q divides k, it is C_q(n-ell*b)/phi(q); when q is coprime to k and ell is a unit modulo q, it is mu(q) C_q(n)/phi(q)²; when q is coprime to k and ell vanishes modulo q, it is C_q(n)/phi(q). The unit case uses an actual permutation of the residue units, not an assumed invariance.

The existing exact odd-prime Cohen evaluation gives norm C_p(n)≤p+1. Splitting p|k, p|ell and p∤k*ell yields the full bound norm G_p(ell,k,n)≤8 gcd(p,k*ell)/p for every odd prime and arbitrary source parameters. The coefficient retains the actual Gauss/Upsilon normalizations. Bounds for arbitrary moduli and for the individual Upsilon sums, together with smoothing and smooth-modulus tails, remain open; no full source arithmetic lemma or completion is claimed.

Checkpoint notes 1167-1241

Checkpoint_1167_GoldbachEuclideanProduct.md

Checkpoint 1167: Actual Euclidean product bounds and both improper tails

The source linear integral is bounded by $N^2/(\ell \log 2)$, uniformly in W, using the actual clamped strict-domain integral. Consequently the genuine product I_U(gamma) J_ell,W(gamma) has the flat bound $N^3/(\ell(\log 2)^2)$ and the decay bound(D/ell) abs(gamma)^(-3/2), where D=(2 quadraticIntegralConstant/log2)/(pi log2)>0.

For every c>0 and either frequency direction sigma with abs(sigma)=1, the actual complex product at sigma*gamma is proved integrable on(c,infinity). Its norm integral is bounded by2D/(ell sqrt c). This is obtained by domination with the actual integrable rpow tail and evaluation of that improper integral. No Fourier-decay, integrability or tail endpoint is an external assumption. These establish the Euclidean tails needed in smoothing; the actual cutoff replacement and full circle-method completion remain open.

Checkpoint_1168_GoldbachPrimePowerBounds.md

Checkpoint 1168: All prime-power coefficients and explicit two-adic bounds

The exact Upsilon normalization phi(gcd(q,k))/phi(q) is proved from the totient lcm identity. Direct finite norm estimates yield norm Upsilon≤phi(gcd(q,k)) and norm $G_q \le q^2$. These coarse bounds are used only to control the finite two-adic cases, not claimed as the required general Upsilon decay.

For every prime p and positive exponent a, the actual source coefficient satisfies norm G_{p^a}(ell,k,n)≤512 gcd(p^a,k*ell)/p^a. At odd primes, only a=1 contributes, by the earlier proved higher-power vanishing. At2, exponents at most3 use the explicit q^2 estimate; exponents at least4 vanish. Thus the two-adic contribution is fully controlled with an absolute constant. General-modulus decay is the next multiplicative deduction; Upsilon decay and actual smoothing/completion remain open.

`Checkpoint_1169_GoldbachArithmeticDecay.md`

Checkpoint 1169: General-modulus arithmetic and Gauss divisor decay

The genuine arithmetic coefficient is bounded at every positive modulus by tau(q)^9 gcd(q,k*ell)/q, uniformly in the source parameters. Its exact multiplicative factorization is combined with the proved prime-power estimates. The gcd ratio gcd(q,c)/q is itself factored by a proved coprime product identity. The elementary inequality2^omega(q)≤tau(q) turns the finite prime-factor weight512^omega(q) into tau(q)^9.

The actual principal square Gauss coefficient also satisfies norm s(a,q)≤tau(q)^3/sqrt(q) at every unit frequency, by the earlier unconditional twisted Gauss estimate and the same divisor comparison. No character bound, Gauss estimate or general-modulus coefficient decay is assumed as an external input. The remaining arithmetic clause in l:arithmeticcoefficients9 is the sharper individual Upsilon decay. The Euler identity, absolute convergence, full G_q decay, Gauss decay and source harmonic sum are now proved; full smoothing/completion and l:circmethod remain open.

`Checkpoint_1170_GoldbachArithmeticFamily.md`

Checkpoint 1170: Actual weighted arithmetic-family and finite-tail estimates

The full actual source family sum of norm G_q divided by ell phi(k) is bounded by9 exp(2) tau(q)^11(log N)²/q, uniformly in the residue family and n. The proof combines the actual general-modulus coefficient decay with the complete source harmonic estimate. The positive modulus and progression indices are justified from the exact strict finite family.

For any finite set S of positive denominators, bounded complex coefficients d, and kernel values H of norm at most a nonnegative M, the actual weighted arithmetic error is bounded by9 exp(2) M(log N)² times sum_{q in S}tau(q)^11/q. All finite sum exchanges and complex normalizations are proved. This applies to the explicit finite support obtained from the Euler series, but does not claim the missing quantitative smooth-denominator tail decay.

The separate progress map lists exactly what is complete and what remains: Upsilon decay, the actual cutoff replacement, addition of separated smooth denominators, the Rankin tail beyond Y, and final circle-method assembly. The full l:arithmeticcoefficients9, l:majorcompletion9 and l:circmethod remain open. The paper ledger is unchanged. No new external input or Lean axiom is introduced, and the selected manuscript is unchanged pending the user's updated source.

`Checkpoint_1171_GoldbachFiniteUnitAverages.md`

Checkpoint 1171: Exact normalized averages under finite unit reduction

The normalized sum of an arbitrary complex function over a finite group is preserved under pullback by a surjective group homomorphism. The proof partitions into fibres, proves all fibre cardinalities equal and positive, and cancels the exact cardinality normalization. It is specialized to the surjective reduction maps on units of ZMod at every positive pair of dividing moduli.

This supplies the exact finite expectation identity needed for reduction of the actual Upsilon frequency to its primitive modulus. No asymptotic equidistribution or prime-distribution input is involved. The full arithmetic, smoothing and circle-method endpoints remain internal obligations. The newer uploaded manuscript was read completely and all58 active mathematical statements match the selected reference; it still contains the endpoint sentence pending the user's proof edit, so no automatic source substitution is made.

The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

Checkpoint_1172_GoldbachPrimitiveProgression.md

Checkpoint 1172: Exact primitive progression cancellation and CRT bound

The actual progression exponential sum vanishes under a nontrivial square-zero translation preserving the progression. Such a translation is constructed whenever the divisor modulus and its complementary factor share a prime. The primitive additive frequency supplies the nontrivial phase, so the cancellation is exact.

In the coprime case, an explicit CRT unit permutation fixes the progression coordinate. The free coordinate gives a genuine Ramanujan sum at a unit, equal to the Mobius function. Consequently its norm is at most one. These primitive-frequency statements are proved directly from the source finite sums and the earlier elementary character identities, with no independent progression-sum estimate.

The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

Checkpoint_1173_GoldbachUpsilonReduction.md

Checkpoint 1173: Exact Upsilon unit expectation and frequency reduction

The actual unit sum is converted exactly to its finite canonical residue range. The lcm-compatible residue sum is identified with a unit sum on ZMod(lcm(k,q)), preserving the source residue restriction and all totient factors. Thus actual Upsilon is expressed as a normalized unit expectation with the source progression fixed.

The normalized pullback theorem proves the exact frequency reduction Upsilon(q*d,k,b,d*beta)=Upsilon(q,k,b,beta), for every positive denominator, multiplier and progression modulus and every coprime source residue. The proof checks both reduction maps and the exact additive-character scaling; no distribution or cancellation estimate is assumed. This is the precise nonprimitive-frequency bridge needed for the missing Upsilon decay.

`Checkpoint_1174_GoldbachUpsilonDecay.md`

Checkpoint 1174: Actual Upsilon gcd decay from primitive frequency reduction

The primitive progression norm bound is proved for every divisor/complement pair, including the exact zero branch. This gives norm Upsilon(q,k,b,alpha)≤gcd(q,k)/phi(q) at every primitive additive frequency and source coprime residue.

The nonprimitive frequency is reduced exactly by d=gcd(q,ell). The quotient frequency is proved primitive, the reciprocal totient is bounded by tau(q)/q, divisor-cardinality monotonicity is checked, and the gcd contribution is transported through the common factor. The actual source coefficient satisfies norm Upsilon(alpha*ell,q,b,k)≤tau(q) gcd(q,k*ell)/q, stronger than the unspecified divisor-power estimate in the paper. No independent Lacey progression estimate or other new input is assumed. Integer residue transport and the common-exponent source arithmetic assembly are next.

`Checkpoint_1175_GoldbachArithmeticComplete.md`

Checkpoint 1175: Full arithmetic coefficient lemma and Euler product

Every clause of l:arithmeticcoefficients9 is now proved for the genuine source coefficients. The integer residue b is reduced to its canonical coprime representative; the Upsilon bound holds for arbitrary integer coprime b. The Gauss, Upsilon and G_q estimates share the absolute exponent C_1=9. Their constants can be chosen1, and the harmonic-family constant is9 exp(2).

The infinite local Euler factors are evaluated directly: all odd prime exponents beyond1 vanish, and the two-adic sum consists exactly of the exponents1,2,3. The full R-smooth series is absolutely summable and equals both the printed all-prime Euler product and the source arithmetic factor G_R. The statements hold for every R≥2, hence for the eventual logarithmic R in Section10. The harmonic theorem retains all strict real family cutoffs, every B≥0, and all positive arithmetic indices.

A clause-by-clause source review closes l:arithmeticcoefficients9 as proved. Positivity and smoothing of the actual singular integral, the full major completion and the final circle-method lemma remain internal obligations. No endpoint from this paper has become an external assumption. The selected manuscript is unchanged.

Checkpoint_1176_GoldbachAutocorrelation.md

Checkpoint 1176: Actual autocorrelation cutoff and inverse Fourier positivity

The paper allows an arbitrary nonzero real smooth compactly supported seed; it does not assume that the seed itself is even or nonnegative. The formal construction now complexifies any real Schwartz seed, reflects it, and takes its genuine convolution. The convolution is proved equal to the actual real autocorrelation integral. Its value at zero is the integral of the seed squared, proved strictly positive from nonzeroness and continuity.

The Fourier transform of the reflection is the conjugate transform of the seed. Consequently the autocorrelation transform is the squared complex modulus. Normalization gives eta(0)=1, and its actual Euclidean inverse Fourier transform is real and nonnegative. These are proved facts, not additional assumptions about the paper kernel. Scaling, support and quantitative smoothing, the singular integral and major completion remain to be assembled.

`Checkpoint_1177_GoldbachScaledCutoff.md`

Checkpoint 1177: Scaled cutoff support and square positivity

Positive Euclidean dilation of a Fourier multiplier has its genuine inverse transform equal to the dilated inverse transform times the positive reciprocal scale. This proves inverse-transform positivity for the actual scaled eta_N, not a newly assumed kernel.

For every Schwartz multiplier with real nonnegative inverse transform, the inverse transform of its square is proved equal to the genuine convolution of its inverse transforms, and is real nonnegative. This applies to the exact eta_N squared in the manuscript.

The seed support inside (-1/8,1/8) gives eta=0 whenever |x|≥1/4. The scaled cutoff therefore vanishes whenever |gamma|≥R/(4N²). All conclusions use ordinary Mathlib Fourier inversion and actual integrals. The full singular-integral positivity and smoothing estimate and the major-completion lemma are not yet claimed.

`Checkpoint_1178_GoldbachCutoffBounds.md`

Checkpoint 1178: All source cutoff bounds from the genuine seed

The normalized autocorrelation cutoff is proved real and even, and its modulus is at most1. The latter follows by integrating the elementary inequality2|uv|≤u²+v² and translation invariance, so it does not require nonnegativity of the original seed.

Evenness gives eta'(0)=0. Bounds on the second derivative of the actual Schwartz cutoff and two applications of the mean value theorem give the uniform quadratic estimate. In particular there exists a positive constant K depending only on the fixed seed such that |1-eta(x)²|≤K min(1,|x|²) for every real x. This is precisely the source cutoff bound before the singular-integral lemma, with its scale dependence retained through the proved dilation formula.

The cutoff properties are now proved from the source construction. They are not new independent hypotheses. The actual singular integral still needs its Fourier inversion, nonnegativity and quantitative comparison, followed by major completion and final assembly.

`Checkpoint_1179_GoldbachIntegrableDecay.md`

Checkpoint 1179: Two-sided Euclidean integrability and quantitative tail assembly

A strongly measurable complex function with a uniform bound M on |gamma|≤c and decay B|gamma|^(-3/2) outside that interval is proved integrable on the entire real line. Its actual L1 norm is at most2Mc+4B/sqrt(c). The proof evaluates both improper tails, controls the finite interval and proves the negative-half-line change of variables.

This general fact supplies the missing analytic justification for applying Fourier inversion to the genuine Euclidean product and for bounding smoothing errors. It has no unproved analytic input. The singular-integral and major-completion source statements remain open until their actual functions are substituted and the final comparisons are proved.

`Checkpoint_1180_GoldbachPositiveFourierAverage.md`

Checkpoint 1180: Exact Fubini identity for positive Fourier kernel averages

Fubini is proved for a genuine Schwartz cutoff and every integrable real weight on a product-space measure. The actual Euclidean frequency integral equals the weighted average of the cutoff inverse transform at the sum frequency. Absolute integrability of the joint integrand is proved from the product of the L1 norms.

If the weight is nonnegative and the cutoff inverse transform is real nonnegative, the resulting actual Fourier integral is real nonnegative. This is the analytic mechanism for positivity of H_(ell,R). It is proved from ordinary integration and Fourier inversion, not postulated. Substitution of the exact paper integrals and the quantitative comparison remain next.

`Checkpoint_1181_GoldbachSingularIntegralPositive.md`

Checkpoint 1181: Actual singular integral positivity for every arithmetic index

The genuine source H_(ell,R)(n;U,W) is now defined using the actual normalized seed cutoff, the exact quadratic integral and the strict progression-domain linear integral.

The product I_U J_(ell,W) is proved equal to its actual positive two-variable density Fourier integral. Substituting that identity into the proved Fubini theorem, and using the already-proved inverse positivity of eta_N squared, proves that H is real and nonnegative. This holds for every real n, all positive ell,N,R, and U,W≥2. If the strict progression domain is empty, the integral is exactly zero; this case is explicitly proved, so no upper bound on ell is hidden in the result.

Thus the full positivity clause of l:positiveH9 is proved. The O(N/sqrt(R)) comparison with the printed one-variable H_ell still needs its quantitative estimate and exact unsmoothed Fourier inversion. The lemma remains open in the ledger until both clauses are complete.

Checkpoint_1182_GoldbachSingularIntegralNorm.md

Checkpoint 1182: Global Euclidean L1 and uniform singular-integral bounds

The genuine Euclidean product I_U J_(ell,W) is proved absolutely integrable over the full real frequency line. Splitting at$1/N^2$ and evaluating both improper tails gives an explicit uniform L1 bound C N/ell, where $C=2/(\log 2)^2+4D$ and D is the previously proved absolute decay constant.

The exact eta_N-squared singular-integral integrand is separately proved integrable and is dominated in modulus by the Euclidean product. Consequently $|H_{(ell,R)}(n;U,W)|\le C\ N$ for every real n and all positive ell, retaining U,W and the exact strict source domain. The empty-domain branch is included. This discharges the uniform kernel bound needed by the arithmetic tail in major completion.

The O(N/sqrt(R)) comparison with the printed H_ell and the full completed major-arc error still remain internal obligations.

Checkpoint_1183_GoldbachSmoothingDecay.md

Checkpoint 1183: Quantitative smoothing error from exact quadratic cancellation

A global quantitative smoothing lemma is now proved. If the actual error multiplier is bounded by K min(1,(|gamma|/c)²) and the other factor decays as D/(sqrt(|gamma|)|gamma|), their product is integrable and its L1 norm is at most6KD/sqrt(c).

The proof handles the zero frequency explicitly, proves the near-zero cancellation algebra, and evaluates both real-line tails. Substituting c=R/N² and the already-proved actual eta cutoff bound gives the scale N/sqrt(R) required by the source. No Fourier identity for the printed H_ell is assumed or claimed here; that identification remains to be proved.

Verification

All 1250 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5043-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 3954 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1252 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

Checkpoint_1184_GoldbachSingularSmoothing.md

Checkpoint 1184: Actual uniform singular-integral smoothing estimate

For the actual normalized seed and exact source I_U,J_(ell,W), the genuine smoothed integral differs from the genuine unsmoothed inverse integral by at most K N/sqrt(R), with K depending only on the fixed seed. The constant is selected before N,ell,R,U,W,n; all positive ell and all real n are included.

The proof substitutes the actual quadratic cutoff bound into the global smoothing lemma, proves every integral used in the subtraction is integrable, and handles the empty progression-domain case exactly. The scale R/N^2 is simplified without dropping ell or endpoint dependence.

The remaining clause for closing l:positiveH9 is the exact identification of the unsmoothed inverse integral with the printed positive one-variable H_ell. This identity has not become an external input. Major completion and final circle-method assembly also remain internal obligations.

`Checkpoint_1185_GoldbachQuadraticDensity.md`

Checkpoint 1185: Exact quadratic density Fourier identity with all integrability conditions

The one-variable density associated with $u^2+a\,v$ is constructed as the actual affine average a^(-1) integral f(u)g((x-u²)/a) du. For every positive real a and arbitrary integrable measurable f,g, its joint integrand and the resulting density are proved globally integrable.

Its genuine Fourier transform is proved equal to the product of the quadratic transform of f and the scaled linear transform of g. The affine change of variables, the scale factor a, and the Fubini integrability are all proved explicitly. This provides the exact analytic route to the printed H_ell, rather than assuming the desired inversion identity.

The source logarithmic densities, pointwise continuity and the final inverse identity are next. No new external analytic input is introduced.

`Checkpoint_1186_GoldbachSourceDensity.md`

Checkpoint 1186: Actual logarithmic density Fourier transform and endpoint continuity

The actual truncated logarithmic density is constructed, proved measurable, integrable and uniformly bounded. Its only possible discontinuities are its two endpoints, and continuity elsewhere is proved directly.

The exact quadratic average with the source cutoffs is proved globally integrable, and its Fourier transform is exactly I_U(-gamma)J_(ell,W)(-gamma). Pointwise continuity of the averaged density is also proved: the exceptional endpoint preimages are the explicitly excluded singleton square roots, which have zero measure. Dominated convergence uses the proved logarithmic bound, so no endpoint regularity is assumed.

These facts discharge every hypothesis of ordinary Fourier inversion for the actual source density. The next assembly identifies the inverse integral with the printed one-variable H_ell and closes the full positivity/comparison lemma.

Checkpoint_1187_GoldbachPositiveSingularComplete.md

Checkpoint 1187: Complete source singular-integral positivity and comparison lemma

Every clause of l:positiveH9 is now proved for the genuine source functions. Fourier inversion applies to the actual continuous integrable logarithmic density, whose transform is exactly I_U(-gamma)J_(ell,W)(-gamma). The source n<N² support condition removes the strict progression restriction in the unsmoothed density, and the result is proved equal to the exact printed integral over2≤u≤U and2≤(n-u²)/ell≤W. Every endpoint and empty-domain case is included.

Combining that exact identity with the proved uniform smoothing comparison and actual-kernel positivity gives the complete lemma. One positive constant, depending only on the fixed seed, is chosen before N,ell,R,U,W,n. The theorem covers every real n<N², every positive ell,N,R and all U,W≥2 with U≤N; the source W≤N² restriction is unnecessary. Thus its range is at least the printed range.

The arbitrary real smooth compactly supported source seed is embedded into Schwartz space with nonzeroness proved. The normalized eta is proved equal to the actual autocorrelation integral divided by its actual squared-mass denominator, so the cutoff construction has not been substituted by an assumed surrogate.

A clause-by-clause source review closes l:positiveH9 as proved. All Section10 source statements are now complete except l:majorcompletion9. That major-completion lemma and the final l:circmethod assembly remain internal obligations. No new external theorem or own-paper endpoint was assumed. The manuscript is unchanged.

Checkpoint_1188_GoldbachRankinEuler.md

Checkpoint 1188: Exact Rankin tail reduction and positive divisor Euler product

The positive Rankin weight tau(q)^11 q^(-1+sigma) is proved multiplicative for every real sigma. Its local prime-power value is computed exactly, and the finite divisor sum is proved equal to the genuine prime-by-prime Euler product.

For every positive sigma,Y and every finite subset of the positive divisors of a nonzero integer, the portion with q>Y is bounded by Y^(-sigma) times that exact Euler product. The inequality is proved from real powers, with all positivity conditions retained. The factorial-cube support already proved for the actual smooth coefficients is a direct admissible specialization.

This proves the algebraic Rankin reduction required by major completion. The uniform logarithmic estimate for the Euler product and the actual major-arc completion still remain to be assembled. The full arithmetic and singular-integral source lemmas remain proved.

`Checkpoint_1189_GoldbachRankinLocal.md`

Checkpoint 1189: Uniform local Rankin Euler-factor bound

A uniform finite geometric estimate is proved, and the polynomial exponent factor is absorbed using the already-proved elementary exponential bound. This gives one positive absolute constant C such that every local Rankin factor satisfies sum_(j=0)^J (j+1)^11 p^(j(-1+sigma))≤1+C p^(-1+sigma), simultaneously for every prime p, sigma≤1/2 and every exponent cutoff J.

The proof uses an explicit auxiliary ratio2^(1/44), proves the resulting geometric ratio is below1, and retains the exact constant term1. That last point is essential for a logarithmic prime product rather than a factor growing once for each prime. No prime-distribution theorem or new external input is used.

Checkpoint_1190_GoldbachRankinLogProduct.md

Checkpoint 1190: Unconditional logarithmic Rankin Euler product and finite tail bound

The local Rankin bounds are assembled into a proved logarithmic Euler-product bound. The small real-power factor satisfies p^(-1+sigma)≤exp(1)/p whenever sigma≥0 and sigma log R≤1. Bernoulli's inequality then bounds each factor by a fixed integer power of1+1/p.

The already-proved elementary prime-product estimate gives a fixed natural exponent K such that the full divisor Rankin sum is at most(M log(2R))^K, uniformly in the supporting integer and its prime-power exponents. Here M=12+2/log3 is explicit. Combining this with the finite Rankin reduction gives the actual tail bound Y^(-sigma)(M log(2R))^K for every finite divisor subset with q>Y. No Mertens theorem, PNT or extra distribution input is assumed.

The eventual source-parameter saving and the major-arc Fourier assembly remain to be completed.

Checkpoint_1191_GoldbachRankinDecay.md

Checkpoint 1191: Actual Rankin parameter decay with arbitrary logarithmic saving

The logarithmic-versus-power argument is proved with explicit sufficient inequalities. A general logarithmic quadratic budget gives the negative exponential Rankin saving while controlling the polynomial Euler-product factor.

For every fixed C≥1,M>0,K and t>0, the genuine parameter expression with R=x^C and Y=exp(x)/(100sqrt(R)) is proved at most x^(-t) for all sufficiently large real x. Every logarithm is evaluated with its positivity assumptions, and the numerical100 and square-root scale are retained. The threshold depends only on the fixed parameters, not on arithmetic moduli or coefficient families.

The final substitution x=log N and the actual smooth-divisor tail are next; the major-completion source statement remains open until the Fourier and arithmetic errors are assembled.

`Checkpoint_1192_GoldbachRankinSource.md`

Checkpoint 1192: Actual source smooth-modulus tail with arbitrary logarithmic saving

The exact source parameters R=(log N)^C and Y=N/(100sqrt(R)) are now substituted into the complete Rankin estimate. For every fixed C≥1 and desired t>0, one natural threshold is chosen before every supporting integer D and every finite divisor subset S. If all prime factors of D are at most R and every q in S exceeds Y, then sum_(q in S) tau(q)^11/q≤(log N)^(-t).

The proof checks R≥2, the positive Rankin exponent, its upper bound1/2, the sigma log R budget, and the exact exp(log N)=N substitution. The threshold is uniform in D,S and all arithmetic coefficient data. This is the arbitrary logarithmic saving used in the source tail argument, proved without a new Mertens or distribution hypothesis.

The actual weighted arithmetic-family tail is next, followed by the remaining small-modulus and disjoint added-modulus major estimates and final assembly.

`Checkpoint_1193_GoldbachRankinArithmeticTail.md`

Checkpoint 1193: Actual weighted arithmetic-family Rankin tail

The source Rankin saving is now applied to the genuine arithmetic-family tail weighted by the actual H_(ell,R). For every desired t>0 and C≥1, one threshold is chosen before all real L,V,B cutoffs, all coprime residues, all bounded complex coefficients, U,W, supporting smooth divisor sets and output integers n.

The proved O(N) bound for H and the full source harmonic/coefficient estimate give the actual tail norm at most(9 exp(2) C_H) N (log N)^(-t). The two logarithmic powers in the harmonic sum are explicitly absorbed by choosing the Rankin saving t+2. Positive indices and the exact strict real family bounds are retained; empty progression domains are already included in the H bound.

This closes the weighted arithmetic tail component of major completion. The full major-completion source statement still awaits the sharp small-modulus Fourier identity, its smoothing comparison and the disjoint added-modulus L2 estimate. No new external hypothesis is introduced.

`Checkpoint_1194_GoldbachArcLiftIntegral.md`

Checkpoint 1194: Exact arc-lift Fourier coefficients and Euclidean energy

A genuine real-frequency function supported in|gamma|<1/2 is lifted to the source circle using the actual centered coordinate. The circle integral is proved equal to the real-line integral by translation invariance and the fundamental-domain measure equivalence; no periodization identity is assumed.

The exact Fourier coefficient of a translated lift is proved equal to exp(-2pi i n r) times the actual Euclidean coefficient. The circle L2 energy is also proved exactly equal to the real-line energy. Bounded strongly measurable source functions are proved to give circle MemLp functions at every exponent.

These identities provide the exact normalization and phase needed for the remaining major-model Fourier estimates, including wrapped arcs.

All 1261 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5054-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4000 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1263 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypoth-

esis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

Checkpoint_1195_GoldbachDisjointArcBessel.md

Checkpoint 1195: Disjoint rational arc lifts and exact Euclidean Bessel bound

Rational arc lifts with denominator bound Y are proved disjoint whenever2epsilon<Y^(-2), using the exact source rational-center separation and the centered real lifts. The result includes wrapped arcs and arbitrary measurable functions supported within the stated radius.

For a finite disjoint family, the actual Fourier coefficients satisfy a Bessel bound by the sum of the exact Euclidean L2 energies. The proof checks circle MemLp, moves the finite sums through genuine integrals, proves the pointwise square-energy identity and applies the already-proved circle Bessel inequality. The Fourier phases and normalizations are the exact ones proved at1194.

This is the elementary analytic mechanism for adding R<q≤Y in major completion. No independent large-sieve or completion hypothesis is assumed.

Checkpoint_1196_GoldbachMajorEnvelope.md

Checkpoint 1196: Uniform Euclidean major-envelope square energy

A single nonnegative measurable Euclidean envelope is constructed from the actual flat and inverse-three-halves decay bounds. It is proved integrable with mass O(N), and its squared integral is proved O(N^4). The L2 estimate follows from its actual uniform O(N^3) bound and the proved L1 mass.

For every positive ell and all source U,W, the genuine product ell|I_U J_(ell,W)| is bounded by this common envelope. The empty progression-domain branch is explicitly included. A general domination theorem then gives the exact L2 energy bound for any strongly measurable local integrand controlled by the envelope.

This supplies the quantitative analytic factor for the disjoint added-modulus estimate. The remaining steps are the actual local arithmetic coefficients, denominator summation and the final major-model identities.

`Checkpoint_1197_GoldbachMajorFamilyIntegrand.md`

Checkpoint 1197: Actual local arithmetic-family major integrand and compact support

The genuine local major-family integrand is now defined from the actual principal Gauss coefficient, Upsilon progression coefficient, bounded family coefficients and Euclidean I_U,J_(ell,W). Its exact source-family norm is proved at most A_q E_N(gamma), where A_q=9 exp(2) tau(q)^6 (log N)^2/(q sqrt(q)). This uses the individual primitive Upsilon decay and the full harmonic-family estimate, with arbitrary integer coprime residues.

The integrand is proved strongly measurable. Multiplication by the actual eta_N squared preserves the norm bound and strong measurability. The smoothed integrand is proved exactly zero for$|\gamma| \geq R/(4N^2)$, directly from the original seed support. Every arithmetic index and strict source family cutoff is retained.

The already-proved envelope energy and disjoint Bessel theorem can now be applied to these actual local functions. The source major-completion and final circle-method endpoints remain open until the denominator sums and exact Fourier identities are assembled.

`Checkpoint_1198_GoldbachCenterArithmetic.md`

Checkpoint 1198: Exact signed rational-center and denominator arithmetic identity

The exact rational-center phase is proved equal to the actual ZMod additive character, including denominator1. The simultaneous negative numerator in the Gauss, progression and output-character factors is handled by a proved unit-group permutation.

Consequently the genuine arithmetic sum over source rational centers, with any denominator weight, is exactly the sum of the source G_q coefficients with that same weight. The proof uses the actual unit-to-rational bijection and retains all integer multipliers and residues. A zero-modulus extension only makes the nondependent function total; all contributing denominators are proved positive.

This is the exact arithmetic identity needed to turn the local Fourier model into the printed completed main term. No Euler factor or Fourier sign is postulated.

`Checkpoint_1199_GoldbachRadialMajorIdentity.md`

Checkpoint 1199: Exact actual smoothed major-family and arithmetic main-term identity

The actual local major-family Fourier expression is proved exactly equal to the arithmetic coefficient expression for every denominator weight and every integrable radial kernel. All finite sums are moved through genuine integrals with their integrability proved or explicitly supplied as ordinary function hypotheses.

For the paper's actual eta_N squared, those integrability hypotheses are discharged for every positive ell, including empty domains. The genuine smoothed rational-center expression therefore equals precisely the sum of d H_(ell,R)/(ell phi(k)) times the source denominator coefficients. Arbitrary denominator masks are retained, so the identity applies both to truncation and to the smooth added moduli.

No normalization, signed numerator, Euler coefficient or singular integral is substituted by an assumed quantity. The remaining completion estimates concern the denominator energy sum and sharp-cutoff comparison.

`Checkpoint_1200_GoldbachDivisorSquareTail.md`

Checkpoint 1200: Finite divisor-power denominator square tail

The finite inverse-three-halves tail is proved directly by integral comparison, including arbitrary finite subsets and real lower cutoffs R≥2. Its bound is4/sqrt(R), with the floor and endpoint conventions checked explicitly.

Combining that with the already-proved elementary divisor growth gives one positive absolute constant K such that sum_(q in S) tau(q)^12/q²≤K/sqrt(R) whenever every q in the finite set S exceeds R. The proof retains the full divisor power12 and has no smoothness restriction or upper denominator bound.

This is the denominator summation needed after counting the primitive numerators in the actual disjoint major-family energy estimate.

esis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1201_GoldbachDenominatorEnergy.md`

Checkpoint 1201: Actual rational-numerator count and added-denominator energy sum

The number of actual source rational centers of each denominator is proved exactly phi(q), including modulus1 and arbitrary denominator filters. No coarse center-count substitution is used in the energy sum.

After multiplying the actual squared local prefactor by phi(q), the denominator contribution is bounded by the fixed tau(q)^12/q^2 weight. The proved finite divisor tail therefore yields one absolute K such that the sum of squared local prefactors over every R<q≤Y is at most K(log N)^4/sqrt(R), uniformly in the real upper cutoff Y.

This is the complete arithmetic denominator-energy sum for the added source moduli; only the already-proved local analytic energy and disjoint Bessel inequality remain to be combined with it.

`Checkpoint_1202_GoldbachAddedMajorBessel.md`

Checkpoint 1202: Actual quantitative added-modulus major-family Bessel estimate

The actual added-modulus Fourier family now satisfies the quantitative Bessel estimate: its squared coefficient sum over any finite output set is at most K N^4(log N)^4/sqrt(R). The constant is chosen before N, the arithmetic family, coefficients, cutoffs, upper denominator bound and output set.

The proof applies the exact actual integrands, their seed-derived support, the rational disjointness theorem, the proved envelope energies and the complete primitive-numerator denominator sum. It retains the elementary geometric conditions epsilon=R/(4N^2)<1/2 and2epsilon<Y^(-2); these will be discharged

for the printed Y=N/(100sqrt(R)). The finite rational set may be any subset of the added denominators, so the source R-smooth restriction is included.

This is the full analytic estimate for adding the intermediate smooth moduli, with no independent completion or large-sieve hypothesis. The remaining work is source parameter geometry and the sharp-to-smoothed small-modulus comparison, followed by final assembly.

`Checkpoint_1203_GoldbachCompletionParameters.md`

Checkpoint 1203: Printed completion geometry and logarithmic error rates

The elementary disjointness conditions are discharged for the exact printed Y=N/(100sqrt(R)), retaining the numerical100. If N≥10000,R≥1 and$R^3 \le N$, thenY≥R, the smoothing support is inside the centered half interval, and the translated supports have the required strict rational separation.

For every fixed C≥1, all these conditions are proved eventually forR=(log N)^C, with one natural threshold before all arithmetic families. A general rate lemma also proves(log N)^j/sqrt(R)≤(log N)^(-A) wheneverC≥2A+2j andlog N≥1. Thus the actual added-modulus bound has the required arbitrary logarithmic saving after choosing C large enough.

The remaining analytic estimate is the sharp-to-smoothed small-modulus comparison; exact source-model and final error assembly follow.

Checkpoint 1206: Exact actual sharp major model identity

The actual product of the square major model and weighted progression major model is identified pointwise with its disjoint rational-arc model. A proved coordinate change from the circle to the real line gives the exact sharp-cutoff Fourier coefficient, and finite Fubini plus the negative-unit permutation converts it to the actual generalCoefficient sum times the actual hard singular integral. Every coordinate, sign, boundary cutoff and finite sum is checked.

Verification

All 1273 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5066-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4052 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1275 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; the Section10/11 analytic and sieve estimates remain open internal obligations. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1207_GoldbachCompletionArithmetic.md`

Checkpoint 1207: Exact arithmetic completion split

The actual initial coefficient sum is identified with its finite divisor support by proving vanishing for every omitted coefficient. The actual Euler factor is then split exactly into q <= R, R < q <= Y, and q > Y. The additional rational centers are identified with the middle divisor sum using the proved smoothed rational Fourier identity. No convergence or coefficient support assumption is added.

`Checkpoint_1208_GoldbachCompletionErrorIdentity.md`

Checkpoint 1208: Actual major-completion error decomposition

The actual major-model coefficient minus the actual completed Euler-factor main term is proved equal to the small smoothing error minus the added-modulus Fourier error minus the far smooth arithmetic tail. This identity consumes the already checked actual integral and arithmetic identities, with all source families and signs retained. The three errors are defined by actual sums and integrals.

Checkpoint_1209_GoldbachCompletionBudgets.md

Checkpoint 1209: Uniform completion budgets and geometry

The elementary logarithmic budgets are checked with explicit sufficient threshold C >= 2 A + 16. The squared pointwise small-modulus error summed over n < N^2 has the required N^4 log(N)^(-A) bound; the Rankin pointwise tail has the same mean-square scale. The actual hard and smooth arc separation inequalities are proved eventually for the chosen Y=N/(100 sqrt R), with all thresholds chosen before arithmetic families.

Checkpoint_1210_GoldbachMajorCompletionBound.md

Checkpoint 1210: Full actual major-completion coefficient bound

The actual major coefficient minus the actual Euler-factor/singular-integral main term now satisfies the full mean-square estimate. The proof consumes the exact three-error identity, the small smoothing bound, the disjoint-arc Bessel estimate for added divisors, and the quantitative Rankin tail. Constants and thresholds precede N, all arithmetic families, coefficients and cutoffs. It proves a stronger coefficient formulation with B >= 0, L <= N^2 and W >= 2. No deep analytic input is assumed by this completion theorem.

Checkpoint_1214_GoldbachFixedSieveComparison.md

Checkpoint 1214: Section11 fixed sieve sets and exact exceptional count

Started Section11 with the actual fixed lower and upper prime sets. The lower comparison and the exact upper exceptional-pair inclusion are proved. Every lost upper pair is indexed by a prime p dividing n, has r=n-p^2, and has multiplier ell dividing n-p^2-1. Finite pair counting gives the complete exact upper comparison with error sum over p|n of tau(n-p^2-1). The actual closed multiplier set and its n-dependent subset are used. No deep input is added; the uniform power error is the next proof obligation.

Checkpoint_1217_GoldbachUpperSieveSequence.md

Checkpoint 1217: Exact upper sieve progression sequence

Proved the exact upper divisibility-sequence count as an untruncated prime-square/progression count at modulus12d and argument n-1. The congruence equivalence is proved in both directions. The progression conditions force the prime-square variable to exceed3 and the other prime to be3 modulo4. The actual closed multiplier set is proved to supply ell=2v with v=3 modulo4 and coprime to6 once z>3. A valid coprime residue is chosen before all n. The actual arithmetic/singular main term plus circle-method remainder identity is exported, with the natural n-1 argument retained exactly.

Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4105 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1287 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

`Checkpoint_1219_GoldbachSieveRootCounts.md`

Checkpoint 1219: Actual root counts, density bounds and multiplicativity

The local root count is the actual finite number

$$\rho_p(a) = \#\{u \in (\mathbb{Z}/p\mathbb{Z})^\times : u^2 = a\}.$$

Opening the prime Ramanujan sum proves the exact identity

$$C_p(a) = p\rho_p(a) - (p-1).$$

The previously proved odd-prime Cohen evaluation then gives $\rho_p(a) = 2$ when its Legendre symbol is1 and0 otherwise. In particular $0 \le \rho_p(a) \le 2$, with zero roots at the zero residue. The progression-restricted solution count is proved equal to $\rho_p(n - \ell b)$; it is a cardinality identity for the actual pair set, not a replacement model.

The lower and upper candidate prime densities are defined with the source's inclusive cutoff $p \le R$. Their denominators are strictly positive for every prime $p > 3$. Both are nonnegative and bounded by $2/(p-3)$, which is strictly below1 for $p \ge 7$. At5, a kernel-checked exhaustive calculation proves that either $\rho_5(n) = 0$, or $\rho_5(n) = 2$ and $\rho_5(n-1) = 0$. This proves that the upper density is at most1/2, including the branch $p > R$, and hence lies in $[0, 1)$ at every allowed prime.

For any real prime density $g(p)$, the explicit function

$$\omega(d) = d \prod_{p|d} g(p)$$

satisfies $\omega(1) = 1$, is multiplicative on coprime natural arguments, and obeys $\omega(p)/p = g(p)$. It is defined at0 as well; the factor d makes that value zero. These statements require no unformalized number-theoretic input.

Scope: these files establish actual root counts, the candidate density bounds, and multiplicativity. The full paper local-density claims remain open until the candidates are connected to the actual normalized Euler products. The subsequent milestone supplies that connection and handles the possible zero upper base factor without dividing by it. The original manuscript is unchanged.

Checkpoint_1220_GoldbachSieveConductor.md

Checkpoint 1220: Actual local Euler factors and prime adjunction

The exact progression coefficient is evaluated whenever $q \mid \ell k$, rather than requiring $q \mid k$. Reduction of units to $\gcd(q,k)$, together with the normalized unit-fiber mass, gives

$$G_q(\ell,k,b,n) = \frac{C_q(n-\ell b)}{\phi(q)}.$$

The proof starts from the already checked character coefficient and proves the finite averaging identity internally. In particular this handles the upper sieve at modulus8 even though its base progression modulus is12 and its multiplier is even.

For every prime, the actual unrestricted Euler factor, with multiplier invertible modulo that prime, is

$$1 + G_p = \frac{p(p-1-\rho_p(n))}{(p-1)^2}.$$

For a fixed progression unit it is $p\rho_p(n-\ell b)/(p-1)$. When the multiplier vanishes modulo the prime, the common factor is $p\rho_p(n)/(p-1)$, which may be zero. The actual unrestricted pair count also satisfies $\#\text{pairs} + \rho_p(n) = p-1$.

Under $24 \mid \ell k$ and $n - \ell b \equiv 1 \pmod{24}$, the small-prime factors are exactly8 at2 and3 at3. Thus the original arithmetic factor is24 times the product over primes $p > 3$ with $p \le R$. Congruent progression residues give equal original coefficients and arithmetic factors.

Adjoining a prime $p > 3$, with $p \nmid k\ell$, and imposing $\ell b \equiv c \pmod{p}$, proves the exact normalized identity

$$\frac{G_R(\ell,kp,b,n)}{\phi(kp)} = \frac{G_R(\ell,k,b,n)}{\phi(k)} \begin{cases} \rho_p(n-c)/(p-1-\rho_p(n)), & p \le R, \\ 1/(p-1), & p > R. \end{cases}$$

Every other prime factor is proved unchanged. The proof multiplies local equalities and uses only the strictly positive unrestricted factor at the newly adjoined prime. It never divides by the complete base arithmetic factor, so common zero obstructions are retained correctly.

Scope: these are exact identities for the original finite character coefficients and Euler products, with no added deep inputs. The source local-density lemmas remain open at this saved milestone; the next milestone proves finite-prime assembly and the exact lower and upper CRT specializations.

Checkpoint_1221_GoldbachSieveDensityFactorization.md

Checkpoint 1221: Complete lower and upper local-density lemmas

Both `l:lowerlocaldensity` and `l:upperlocaldensity` are proved for the retained source context. No new external input is used. The selected manuscript is unchanged. The clause-by-clause source review is in `verification/section11-local-density-source-review1221.json`.

The root count is the actual cardinality of the units satisfying the square equation. Consequently zero is excluded from the variable being squared, and rho is zero at the zero residue. Opening the prime Ramanujan sum proves

$$C_p(a) = p\rho_p(a) - (p-1), \qquad \rho_p(a) = \begin{cases} 2, & (a/p) = 1, \\ 0, & (a/p) \neq 1. \end{cases}$$

The normalized character coefficient agrees with the earlier original definition. Its unrestricted factor, when the multiplier is invertible, is

$$1 + G_p = \frac{p(p-1-\rho_p(n))}{(p-1)^2}.$$

If the progression fixes its unit variable to b, the factor becomes

$$1 + G_p = \frac{p\rho_p(n-\ell b)}{p-1}.$$

The proof also checks the multiplier-zero case, whose common factor can vanish. The actual unrestricted pair cardinality plus rho equals p-1.

The finite coefficient identity for q dividing ell*k is needed at the small primes. It is proved from reduction of units and their exact normalized fiber mass. Under the source congruence n-ell*b=1 modulo24, this gives the factor8 at2 and3 at3. In particular, the upper modulus12 with its even multiplier is treated correctly at8.

Adjoining one prime p>3 to a coprime progression modulus proves an identity between the original normalized arithmetic factors. The identity multiplies by

$$g(p) = \begin{cases} \rho_p(n-c)/(p-1-\rho_p(n)), & p \le R, \\ 1/(p-1), & p > R, \end{cases}$$

when ell*b=c modulo p. The cutoff is inclusive, including a prime equal to R. Every other prime factor is proved unchanged. Induction over a finite set of distinct primes, followed by the square-free prime-factor product identity, proves the full factorization for d.

For the lower sieve, the actual CRT conditions are b=11 modulo24 and b=1 modulo d, while n=12 modulo24. They give c=1. The base arithmetic factor at modulus24 is proved nonzero, so the paper's original quotient definition is identified with this density. The prime formula is proved for every p>3; the lower sieve's additional restriction p=3 modulo4 is therefore included.

For the upper sieve, the existing source multiplier result supplies ell=2v and v coprime6. The actual conditions vb=5 modulo12 and ell*b+1=0 modulo d imply the required congruence at24 and give c=-1 at every divisor prime. Unit cancellation shows that every representative reduces to the same base class modulo12. The resulting density is

$$g_{n,\ell}(p) = \begin{cases} \rho_p(n)/(p-1-\rho_p(n-1)), & p \le R, \\ 1/(p-1), & p > R. \end{cases}$$

One explicit function omega(d)=d times the product of these prime densities is constructed before all supported square-free d and all representatives of the source CRT classes. Its value at1 and its multiplicativity on coprime arguments are proved. The complete existence and factorization statement is `goldbach_upper_local_density`.

The denominator is positive for p>3. Both candidate densities are nonnegative and at most 2/(p-3), which is below1 for p>=7. At5, a kernel-checked finite calculation gives either rho_5(n)=0, or rho_5(n)=2 and rho_5(n-1)=0. The upper density is therefore at most1/2 at5. This proves its full required range [0,1).

The upper identity never divides by its base arithmetic factor. If a common obstructing local factor is zero, the multiplicative identity still proves equality with zero on both sides. A zero base is not an extra hypothesis or an omitted case.

The paper-level ledger is now19 proved claims,27 complete conditional implications,1 quoted external result and7 open claims, with4 definitions separate. Presieving and the later sieve estimates remain open. The later analytic use of these densities does not retroactively become an input to the local-density proofs.

`Checkpoint_1222_GoldbachPresieveCoefficients.md`

Checkpoint 1222: Finite presieving coefficients, sequence bounds and quantitative error

The finite two-stage construction is proved in Lean. The original source lemma remains open: its dimension hypothesis must be corrected before the classical coefficient theorem can supply the stated sieve functions. Proposed replacement passages are in `Section11_Presieving_Replacements.tex`. They have not been applied to the selected manuscript.

The primary source checked is Yuta Suzuki's The Rosser–Iwaniec sieve, dated14 March2023. Definition8.2 requires the product bound with factor 1+K/log(w), rather than an unrestricted fixed factor K0. Lemma14.7 states the corresponding coefficient estimates with D>=z>=2. Proposition11.8 controls the sieve-function tails. The original official Iwaniec1980 PDF downloads returned403; this review does not claim they were read.

Three points need to be explicit in the manuscript. First, the refined dimension estimate is stronger than a coarse implied-constant estimate. A fixed K0 allows a concentration of local mass at a few large primes, while 1+K/log(w) approaches1 at large w. Consequently the coarse estimate alone is not the hypothesis of the cited coefficient theorem. The refined interval forms of Mertens' theorem are available for the actual outer densities in this application; they must be stated and used.

Second, the preliminary prime set includes p=R. A dimension condition restricted to p<y with y<=R omits that endpoint if R is prime. The proposed formulation bounds the truncated preliminary prime set over all relevant intervals and uses sifting limit R+1. This retains exactly the intended primes p<=R.

Third, D0<D by itself does not place the outer sieve in the range D1>=z, and log(D0)/log(R) tending to infinity by itself does not give the rate needed to absorb arbitrary outer logarithmic losses. The proposed passage states the actual scale R=(log N)^C, the bound R+1<=z<=D1<=N^A, and the intended uniformity. These conditions give preliminary relative errors bounded by a constant times exp(-c(log log N)^2), which dominate every fixed negative power of log N. Applying these scale conditions to the final lower and upper sieve parameters is a separate later obligation.

The checked finite construction does not assume the paper's two-stage conclusion. It starts from independent one-stage lower and upper weight inequalities. For an outer lower coefficient u(d), the preliminary choice is the lower weight when u(d)>=0 and the upper weight when u(d)<0. For an outer upper coefficient, the choices are reversed. Lean proves the resulting pointwise inequalities, then sums them over actual finite sequences. The sequence is represented by a finite set of indices and an arbitrary integer-valued map, so repeated values are counted correctly.

Disjoint prime supports imply coprimality of every preliminary divisor e and outer divisor d. This gives unique decomposition of m=e*d. The flattened coefficient is explicitly the sum over pairs with that product. Lean proves its absolute value is at most1 and that it vanishes for m>=D0*D1. It also proves exact reindexing into the sum over all natural m<D0*D1, using the natural ceiling of the real level. None of these coefficient definitions mentions the density function, the sequence, X or the remainders.

For the main term, let V0 be the preliminary Euler product, and suppose each preliminary coefficient sum differs from V0 by at most epsilon0*V0. The error from either signed selection is proved to be at

most

$$\varepsilon_0 V_0 \sum_d |u(d)|g(d).$$

Together with the outer coefficient estimates, this proves explicit finite lower and upper inequalities with the original signed remainders. No positivity assumption on an outer signed weight is introduced. The asymptotic coefficient theorem, the uniform Euler-product growth bound and the rate absorption must still be joined before calling the full corrected asymptotic lemma complete.

The source-level ledger remains19 proved claims,27 complete conditional implications,1 quoted external result and7 open claims. The presieving supporting theorems do not increase that count by themselves.

Checkpoint_1223_GoldbachPresieveDecay.md

Checkpoint 1223: Presieve Euler mass, exact scales and uniform error decay

The outer coefficient mass is bounded for the actual square-free divisor support. The proof first derives the prime-product expression from multiplicativity on supported square-free integers; no stronger global multiplicativity hypothesis is used. Injectivity of the prime-factor set on square-free integers then embeds the divisor sum into a sum over subsets of the outer prime set. Expanding the Euler product gives

$$M = \sum_d |u(d)|g(d) \le \prod_{p\in\mathfrak{P}_1}(1+g(p)), \qquad \frac{M}{V_1} \le V_1^{-2}.$$

Every factor of V1 is strictly positive. The estimate uses only0<=g(p)<1 and |u(d)|<=1; the outer weights may have either sign.

Given the dimension product bound at w=2 and log(z)<=A*log(N), the inverse outer Euler product is at most

$$K_2(\log N)^\kappa, \qquad K_2 = (1+K/\log 2)(A/\log 2)^\kappa.$$

The finite preliminary error therefore has a uniform logarithmic majorant independent of the density function.

Write t=log(log(N)), D0=exp(t^3), and use preliminary sifting limit exp(C*t)+1. Lean proves

$$s_0 \ge \frac{t^2}{C+1}$$

for t>=1, proves s0 tends to infinity, and proves D0 eventually exceeds that sifting limit. Gaussian decay against every fixed exponential-linear factor and power of t is proved from Mathlib's exponential asymptotics. Consequently the preliminary error K0*exp(-c*s0) absorbs every fixed power of log(N).

If D1 is at least exp(C*t)+1 eventually, it tends to infinity. For every delta>0, the outer error K1*(log(D1))^(-delta) tends to zero. Combining these deductions proves the exact common error rate used in the next assembly:

$$K_1(\log D_1)^{-\delta} + K_0 e^{-cs_0}\big(K_2(\log N)^\kappa\big)^2 \longrightarrow 0.$$

All these arithmetic and limit deductions are proved internally. The independent classical one-stage coefficient theorem is not used as an input to this milestone. The next milestone connects its two explicit interfaces to these bounds and proves the corrected full presieving implication. The original weaker manuscript statement remains unclaimed, with proposed replacements saved separately.

`Checkpoint_1224_GoldbachPresieveUniformAssembly.md`

Checkpoint 1224: Corrected full presieving from independent classical inputs

The corrected full presieving implication is proved in `goldbach_corrected_presieving`, conditional on the independent general one-stage Rosser–Iwaniec fundamental and coefficient inputs. Their exact interfaces are documented in `docs/EXTERNAL_SIEVE_INPUTS.md`. The literal original source lemma remains open until its weaker hypotheses are corrected. Proposed replacement passages are in `Section11_Presieving_Replacements.tex`. They have not been applied to the selected manuscript.

The primary source checked is Yuta Suzuki's The Rosser–Iwaniec sieve, dated14 March2023. Definition8.2 requires the product bound with factor 1+K/log(w), rather than an unrestricted fixed factor K0. Lemma14.7 states the corresponding coefficient estimates with D>=z>=2. Proposition11.8 controls the sieve-function tails. The original official Iwaniec1980 PDF downloads returned403; this review does not claim they were read.

The corrected statement explicitly requires X>=0 and g(1)=1; X=0 is included. Three further points need to be explicit in the manuscript. First, the refined dimension estimate is stronger than a coarse implied-constant estimate. A fixed K0 allows a concentration of local mass at a few large primes, while 1+K/log(w) approaches1 at large w. Consequently the coarse estimate alone is not the hypothesis of the cited coefficient theorem. The refined interval forms of Mertens' theorem are available for the actual outer densities in this application; they must be stated and used.

Second, the preliminary prime set includes p=R. A dimension condition restricted to p<y with y<=R

omits that endpoint if R is prime. The proposed formulation bounds the truncated preliminary prime set over all relevant intervals and uses sifting limit R+1. This retains exactly the intended primes p<=R.

Third, D0<D by itself does not place the outer sieve in the range D1>=z, and log(D0)/log(R) tending to infinity by itself does not give the rate needed to absorb arbitrary outer logarithmic losses. The proposed passage states the actual scale R=(log N)^C, the bound R+1<=z<=D1<=N^A, and the intended uniformity. These conditions give preliminary relative errors bounded by a constant times exp(-c(log log N)^2), which dominate every fixed negative power of log N. Applying these scale conditions to the final lower and upper sieve parameters is a separate later obligation.

The checked finite construction does not assume the paper's two-stage conclusion. It starts from independent one-stage lower and upper weight inequalities. For an outer lower coefficient u(d), the preliminary choice is the lower weight when u(d)>=0 and the upper weight when u(d)<0. For an outer upper coefficient, the choices are reversed. Lean proves the resulting pointwise inequalities, then sums them over actual finite sequences. The sequence is represented by a finite set of indices and an arbitrary integer-valued map, so repeated values are counted correctly.

Disjoint prime supports imply coprimality of every preliminary divisor e and outer divisor d. This gives unique decomposition of m=e*d. The flattened coefficient is explicitly the sum over pairs with that product. Lean proves its absolute value is at most1 and that it vanishes for m>=D0*D1. It also proves exact reindexing into the sum over all natural m<D0*D1, using the natural ceiling of the real level. None of these coefficient definitions mentions the density function, the sequence, X or the remainders.

For the main term, let V0 be the preliminary Euler product, and suppose each preliminary coefficient sum differs from V0 by at most epsilon0*V0. The error from either signed selection is proved to be at most

$$\varepsilon_0 V_0 \sum_d |u(d)|g(d).$$

Together with the outer coefficient estimates, this proves explicit finite lower and upper inequalities with the original signed remainders. No positivity assumption on an outer signed weight is introduced. The uniform Euler-product bound and exact rate absorption are now proved and joined to the two independent classical one-stage interfaces in the complete corrected asymptotic deduction. No own-paper endpoint is assumed.

The source-level ledger remains19 proved claims,27 complete conditional implications,1 quoted external result and7 open claims. The presieving supporting theorems do not increase that count by themselves.

The signed outer mass M is proved to satisfy M/V1<=V1^(-2). The refined dimension condition at w=2 and log(z)<=A*log(N) give V1^(-1)<=K2*(log N)^kappa, with K2=(1+K/log 2)*(A/log 2)^kappa. Multiplicativity is needed only on supported square-free integers; its prime-product expression is proved internally.

For t=log(log N), D0=exp(t^3), and preliminary sifting limit exp(C*t)+1, the exact preliminary parameter satisfies s0>=t^2/(C+1) for t>=1. Lean proves this bound, eventual level admissibility and s0 tending to infinity. The explicit common relative error

$$\varepsilon(N) = K_1(\log D_1)^{-\delta} + K_0 e^{-cs_0}\big(K_2(\log N)^{\kappa}\big)^2 \longrightarrow 0$$

is proved uniformly before all admissible densities. For every sufficiently large N, the final coefficients are chosen before g, the finite sequence, X and the remainders. In the paper application they are therefore chosen before n. The main terms contain only the outer functions f_kappa and F_kappa. The natural-absolute-value bridge covers repeated and negative integer sequence values.

The original manuscript is unchanged. The corrected complete conditional variant is recorded separately from the literal-source inventory. Its independent one-stage inputs and classical function normalization remain unproved; the kernel audit verifies the consuming implication. The next mathematical milestone is the actual lower-sieve application.

Verification

All 1304 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5097-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4204 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1306 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. The rational smooth multifrequency theorem with circle transference remains an explicit independent compound hypothesis. The classical primitive sum-of-two-squares criterion is an additional explicit independent arithmetic hypothesis for Section9 reductions; it contains no own-paper conclusion and is not declared as a Lean axiom.

Checkpoint_1225_GoldbachLowerSieveParameters.md

Checkpoint 1225: Actual lower-sieve levels and refined density conditions

The actual lower-sieve levels D=N/(24(log N)^B), D1=D/exp((log log N)^3), and z=N^(8/9) now have a proved normalized logarithmic limit log(D1)/log(N) -> 1 and sieve-parameter limit log(D1)/log(z) -> 9/8. The entire admissible range R+1<=z<=D1<=N^2 is proved eventually for every fixed B and C, and D0*D1=D is exact. The finite prime set and its disjoint preliminary/outer split are explicit. The actual unit-square local densities yield a supported multiplicative density with all prime factors in [0,1). Both refined dimension conditions are proved from independent classical interval Mertens products. The preliminary majorant is 2/(p-3), p>=7, of dimension2; the outer product is the ordinary p=3 mod4 comparison of dimension1/2. This input contains no n, Goldbach sequence, presieve conclusion, or own-paper endpoint. The real lower application and circle-error assembly remain to be joined. The manuscript is unchanged while the user edits the supplied replacements.

Classical interval Mertens products for the universal majorant and the progression3 mod4 are additional independent arithmetic inputs; no own-paper endpoint is assumed.

`Checkpoint_1226_GoldbachLowerSieveBridge.md`

Checkpoint 1226: Actual lower main term and circle remainder estimate

The actual lower sequence is now joined to the original arithmetic factor and smoothed singular integral. The base arithmetic factor is proved real and strictly positive at n=12 mod24; positivity of the singular integral proves X_n>=0 without a new assumption. CRT residue classes are fixed before n and are chosen to be units for every denominator. The exact real divisor-count identity and the sifted-count identity use the actual prime-square representations. The lower remainder sum is proved to satisfy the full N^4(log N)^(-A) mean-square bound, uniformly over every real coefficient family with absolute values at most1. This is a deduction from the existing ordinary SW/BV and Ren/Ghosh inputs, via the already checked circle-method theorem. The embedding d -> (1,24d), its injectivity, strict real modulus levels, reindexing and real-part norm comparison are all proved. A zero extension at denominator0 avoids an artificial zero-modulus term. The final presieve and limiting sieve-function assembly remain next. The selected manuscript is unchanged.

Checkpoint_1227_GoldbachLowerSieveApplication.md

Checkpoint 1227: Complete lower-sieve application and mean-square error

The full lower-sieve application, stable source label `p:sieveneedlower8`, is proved in `goldbach_lower_sieve_complete`. This is a complete implication under independent classical inputs, not an unconditional formalization of those inputs. Both clauses of the source proposition are covered.

For every positive prescribed logarithmic saving A, the theorem constructs fixed B>=0, C>0 and M>0, a common real error eta(N) tending to zero, and for every sufficiently large integer N a coefficient family c_d chosen before n, with |c_d|<=1. For every n=12 mod24 it proves

$$X_n\Theta_n(z)(f_{1/2}(9/8)-\eta(N))+\mathcal{E}_1(n)\le S(\mathcal{A}_n,\mathbb{P}_{3,n},z),\qquad z=N^{8/9},$$

and

$$\sum_{n<N^2}\mathcal{E}_1(n)^2\le MN^4(\log N)^{-A}.$$

The pointwise statement actually holds for every n in that residue class, so it includes the entire retained n range uniformly for every A0. The error is uniform because it is fixed before n; no density-dependent o(1) is introduced.

Actual levels and the common error

The definitions use D=N/(24(log N)^B), D0=exp((log log N)^3), D1=D/D0 and R=(log N)^C. Lean proves log(D1)/log(N)->1, log(D1)/log(z)->9/8, D0*D1=D, and the eventual complete range R+1<=z<=D1<=N^2. Thus the classical one-stage theorem is used in its admissible range.

Write epsilon(N) for the already proved explicit uniform presieving error. The new error is exactly

$$\eta(N)=\varepsilon(N)+\left|f_{1/2}(\log D_1/\log z)-f_{1/2}(9/8)\right|.$$

The first summand tends to zero by the quantitative presieve, and the second by the proved parameter limit and continuity of the classical sieve function at9/8. Positivity of the actual X_n and Theta_n permits the lower replacement. No numerical value or positivity of f_(1/2)(9/8) is assumed or needed here.

Actual sequence and main term

The sequence consists of r-1 for the actual admissible representations n=m^2+r with m and r prime and r=11 mod24. The finite-index representation counts each admissible r once, and the image r->r-1 is proved injective on this set. Its divisibility counts are exactly the progression counts with one CRT residue a_d modulo24d. Those residues are fixed independently of n. Their coprimality and congruences are proved, not supplied as new hypotheses.

The density is the product over prime factors of the actual root-count density rho_p(n-1)/(p-1-rho_p(n)) for p<=R, and 1/(p-1) for p>R. Multiplicativity, normalization at1, the interval[0,1), and both refined dimension conditions are proved. The preliminary condition is obtained from the universal majorant2/(p-3) on p>=7, with dimension2. The outer condition has dimension1/2 on the fixed primes3 mod4.

X_n is the real part of the original arithmetic factor G_R(1,24,n)/phi(24) times the original smoothed singular integral. Lean proves the base factor real and strictly positive for n=12 mod24, and uses the already proved singular-integral nonnegativity. The divisor-count expansion uses this exact X_n and the original circle-method remainder. Theta_n is exactly the Euler product of the same local densities. The two split Euler products are proved to equal it.

The corrected presieving construction chooses coefficients before all density functions, finite sequences and n. Its actual fixed-prime sifted count is bounded above by the original n-dependent sifted count using the previously proved fixed-sieve comparison.

Mean-square remainder

The remainder is the real signed sum over positive d<D of the original r_(24d,1)(n), with the fixed CRT residues. The embedding d->(1,24d) into the circle-method coefficient set is proved injective. Its moduli satisfy the strict bound24d<N(log N)^(-B). The coefficients have complex norm at most1. Thus the already proved circle-method theorem applies with the constant multiplier range L=2 and, for example, delta=1/2. Reindexing and |Re(z)|<=|z| give the stated real mean-square estimate. The zero denominator is assigned remainder0, so it introduces no artificial term.

Independent hypotheses and limits

The exact unproved inputs consumed are ordinary prime Siegel-Walfisz, ordinary Bombieri-Vinogradov, the existing raw Ren/Ghosh estimates, the general one-stage Rosser-Iwaniec fundamental and coefficient estimates, the two general interval Mertens products, and continuity of the classical lower sieve function at9/8. The last property is part of the classical sieve-function boundary. All are theorem parameters or proposition-valued interfaces; none is a new Lean axiom. The Mertens interface mentions only arbitrary prime intervals and universal comparison factors. It contains no n, Goldbach sequence, source presieve, lower-sieve proposition or own-paper endpoint.

The selected manuscript is unchanged. The user is editing the compact presieving replacements; their application is not claimed without a new source or confirmation. No further manuscript replacement was found necessary for this lower-sieve milestone.

Remaining work

Five substantive Goldbach claims remain: `l:maintermsize8`, `l:wumatomakisum`, `p:sieveneedupper8`, `l:numericalcomparison`, and `t:repmotthm`. The literal weaker presieving statement remains separately open pending manuscript synchronization, while its corrected conditional variant is already proved. The source ledger is now19 proved,28 complete conditional implications,1 quoted external theorem and6 open claims, plus4 definitions. Checkpoint numbers and supporting-theorem counts are not completion percentages.

The main-term size, weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1228_GoldbachArchimedeanLower.md`

Checkpoint 1228: Explicit archimedean and arithmetic product lower bounds

The lower-bound ingredients now include a kernel-checked explicit archimedean integral estimate and quantitative bounds for the actual local products. For64<=n<=N^2, the interval[sqrt(n)/4,sqrt(n)/2] lies inside the original integration domain. On it, the integrand is at least1/(2(log N)^2). Integrability, global nonnegativity, restriction monotonicity and the exact interval measure are proved, yielding H1(n)>=sqrt(n)/(8(log N)^2). The singular integral is the original one; no artificial substitute main term is introduced.

For every prime p>=7, the unrestricted arithmetic local factor is at least1-2/(p-3); the prime5 factor is at least1/2. The original arithmetic factor is exactly24 times the product of these real factors. From the already recorded general interval Mertens input, Lean proves its lower bound12/((1+K/log2)(log(R+1)/log2)^2). It also proves the uniform inverse bound Theta_n(z)^(-1)<=(1+K/log2)(log z/log2)^2 for the actual lower Euler product. These estimates hold uniformly in n. No new external analytic input is used. Smoothing absorption, a C-independent logarithmic exponent, and common-cutoff compatibility remain to be assembled before closing l:maintermsize8.

The main-term size, weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1229_GoldbachLowerCutoffFreedom.md`

Checkpoint 1229: Common arbitrarily large cutoff for the full lower sieve

The circle-method and lower-sieve estimates now permit any prescribed minimum cutoff exponent Cmin. The proof selects C=max(max(CC,CM),Cmin) in the existing major/minor assembly and verifies every earlier threshold explicitly. The cutoff and full circle estimates, selected signed remainder estimates, lower mean-square estimate and full lower-sieve application are all exported with Cmin<=C. Thus enlarging C for the main-term smoothing argument is an actual theorem, rather than an inferred monotonicity assertion. No previous Lean proof is edited and no additional analytic hypothesis is used. Both lower-sieve clauses hold for one common selected R=(log N)^C, with all coefficients still chosen before n. The quantitative main-term size and its joint application are the next step.

`Checkpoint_1230_GoldbachLowerMainTermSize.md`

Checkpoint 1230: Complete lower-bound side with uniform main term and common cutoff

All mathematical source claims on the lower-bound side are now complete in the agreed conditional scope. The new main-term endpoint is `goldbach_lower_main_term_size`, matching `l:maintermsize8`. The existing full lower-sieve proposition is strengthened to allow any prescribed minimum cutoff exponent. Their joint application is `goldbach_lower_bounds_complete`, which uses the same chosen R=(log N)^C throughout.

Uniform actual main-term lower bound

For every A0>0, every fixed C>=A0+6, and all sufficiently large integer N, Lean proves uniformly for n=12 mod24 and N^2(log N)^(-A0)<=n<N^2 that

$$X_n\Theta_n(z) \geq k_C N(\log N)^{-(A_0/2+6)}, \qquad z = N^{8/9}, \qquad k_C > 0.$$

Thus C_(A0)=A0/2+6 is an explicit admissible exponent, independent of C. This is the exact uniformity required by the source lemma. The quantities are the actual original arithmetic factor, smoothed singular integral and local-density Euler product; no replacement main term is assumed.

For the dimension constant K, let L=(1+K/log2)/(log2)^2. The proof gives the explicit choice

$$k_C = \frac{3}{32L^2(C+1)^2}.$$

K and the smoothing seed are fixed classical/construction parameters, so the implied constant has the dependencies allowed in the paper.

Archimedean lower bound and smoothing

For64<=n<=N^2 the interval[sqrt(n)/4,sqrt(n)/2] lies inside the original domain2<=u<=N,2<=n-u^2<=N^2. On it the integrand is at least1/(2(log N)^2). Integrability, nonnegativity, interval restriction and the real part of the original complex integral are proved. Therefore

$$H_1(n) \geq \frac{\sqrt{n}}{8(\log N)^2} \geq \frac{N}{8(\log N)^{A_0/2+2}}.$$

The retained n range eventually implies n>=64; this growth claim is proved. The already proved smoothing estimate has error at most K_psi N/sqrt(R). If C>=A0+6, then for sufficiently large N this is at most N/(16(log N)^(A0/2+2)), uniformly over the retained n range. Hence the actual H_(1,R)(n) is at least N/(16(log N)^(A0/2+2)). No positivity or lower estimate for this actual function is a new hypothesis.

Actual local products

Every unrestricted factor p(p-1-rho_p(n))/(p-1)^2 with p>=7 is at least1-2/(p-3); the prime5 factor is at least1/2. The original arithmetic factor is proved to be exactly24 times their real product. The already recorded independent interval Mertens input gives

$$G_R(1,24,n) \geq \frac{12}{L(\log(R+1))^2} \geq \frac{12}{L(C+1)^2(\log N)^2}.$$

Separately, the same input and the actual local density bound give Theta_n(z)^(-1)<=L(log z)^2<=L(log N)^2. Together with phi(24)=8 and the smoothed archimedean lower bound, these yield the stated k_C and exponent. This direct product proof does not assume the paper's own main-term estimate or the more precise asymptotic normalization used in the later weighted upper calculation. That normalization remains part of the upper-side work; it is not needed to close this source lower-bound lemma.

One common sufficiently large cutoff

The earlier circle-method theorem returned an exponent C, but did not by its statement alone allow C to be enlarged. The new theorems explicitly select C=max(max(CC,CM),Cmin) in the original major/minor assembly. All applicability thresholds are checked again. The cutoff and full circle estimates, selected signed remainder estimate, lower mean-square estimate and complete lower-sieve application are exported with Cmin<=C.

Taking Cmin=A0+6 proves the lower-sieve inequality, its N^4(log N)^(-A) mean-square remainder estimate, and the actual main-term size simultaneously for one shared C and coefficient family chosen before n. This removes the possible mismatch between an existence statement for C and the smoothing requirement on C.

Positive coefficients and exceptions

Lean proves positivity of the explicit classical half-sieve value sqrt(8 exp(gamma)/(9 pi))*log2 for every real gamma. The classical sieve-function identification/normalization remains in the already recorded classical input boundary; this positivity lemma does not claim to reconstruct that deep theory.

The finite deduction from the lower inequality to positive counts is proved: if v>=T>0, f>0, eta<=f/2 and count>=v(f-eta)+E, then E>=-Tf/4 implies count>=Tf/4. The associated exceptional-set estimate is also proved:

$$\#\{n \in I : \mathrm{count}(n) < Tf/4\}(Tf/4)^2 \leq \sum_{n \in I} E(n)^2.$$

It is a general finite algebraic consequence, ready to apply to the actual common-cutoff lower theorem. No new own-paper endpoint is an external assumption. The numerical comparison with the upper sieve constant and the final Goldbach exceptional-set theorem are separate remaining results.

Conditional scope and source synchronization

No new deep hypothesis was introduced in this continuation. The main-term size consumes only the already recorded general interval Mertens products; its archimedean and smoothing arguments are internal proofs. The joint lower estimate retains the earlier ordinary SW/BV, raw Ren/Ghosh, general one-stage sieve, interval Mertens and classical function-continuity inputs. None is declared as a new Lean axiom.

The selected manuscript is unchanged. The user is editing the compact presieving replacements, and no completed edited source is claimed. Two minor notation corrections in the lower-bound exposition are saved in `blueprint/Section11_LowerBound_Notation_Fixes.tex`: use A0 in the final lower bound of e:H1elementary10 and in the smoothing-choice sentence of the main-term proof. These change notation, not the statements or mathematical argument.

The source ledger is now19 proved,29 complete conditional implications,1 quoted external theorem and5 open claims, plus4 definitions. Four open claims are substantive: the weighted upper main-term comparison, full upper sieve application, strict normalized numerical comparison and final Goldbach assembly. The fifth is the original weaker presieving statement awaiting manuscript synchronization. Supporting-theorem and checkpoint counts are not completion percentages.

Verification

All 1315 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5108-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4259 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1317 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. No new deep input was introduced. Main-term size consumes the existing interval Mertens input; joint lower sieve uses the previously recorded ordinary SW/BV, Ren/Ghosh and general classical one-stage sieve/function-continuity inputs. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

Checkpoint_1231_GoldbachWeightedLocalFactors.md

Checkpoint 1231: Weighted upper local cancellations and uniform prime weights

The first weighted upper-main-term component is checked. The local joint factor U_p, the exact prime weights h_R(p), their multiplicative extension, and B_R(n), C_R(n) are concrete definitions. Lean proves positivity of the joint denominator for every prime p>3, treating p=5 by the finite consecutive-residue calculation. It proves 0<=h_R(p)<=6 uniformly, both exact small-prime cancellation identities, the lower and upper local-density cancellations, multiplicativity and nonnegativity of h_R, and 0<B_R(n)<=C_R(n).

No new external input is used. These are internal arithmetic steps of l:wumatomakisum, not a proof of the full weighted comparison. Remaining: exact finite-product assembly with the original G and Theta; uniform multiplicative mean values and weighted summation; integration, smoothing and the final normalized constant. The source-level claim stays open. The large-m cutoff in Step6 must remain explicit; its displayed logarithmic-power integral cannot literally be extended to every m>0 without an indicator. The selected manuscript remains unchanged.

The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. No new external input in the local weighted upper arithmetic. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1232_GoldbachWeightedEulerProducts.md`

Checkpoint 1232: Original upper arithmetic products and multiplier geometry

The weighted upper quantities are now literal definitions: a canonical reduced base residue modulo12, the original arithmetic/smoothed-integral main term X_n(ell), its finite local-density product Theta, and the unrestricted or zero-multiplier arithmetic factors. Lean proves the base residue has the required congruence and is coprime to12; the original G_R(ell,12,n-1) is exactly24 times its real prime-factor product. Every factor is nonnegative and Theta is strictly positive. The lower small-prime normalization is exactly24*C_R(n), including both residue classes modulo4.

The multiplier geometry is also fully checked for every member of the actual closed L set, with z=N^(8/9): ell<N^(10/9), u<z_ell, N^(2/9)<z_ell<z<=p2, and in fact z_ell<p2. This includes z<=p2 rather than the unsupported strict endpoint in the printed intermediate argument. No new deep input is used. The full weighted source claim is still open; no uniform mean value or weighted-integral conclusion has been assumed.

The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1233_GoldbachWeightedMeanInputs.md`

Checkpoint 1233: Uniform prime balance and effective mean-value instantiation

The varying multiplicative weights now have a checked quantitative prime logarithmic balance. For every y>=R>=3, uniformly in n, the absolute value of sum_{p<=y}(h_R(p)-1/2)log(p)/p is at most6 log R+10K, from the independent ordinary/progression logarithmic Mertens input. The strong prime-power rule and the equality at prime arguments are checked.

The general nonnegative strongly multiplicative upper corollary of Tenenbaum's corrected effective Wirsing theorem is an explicit independent proposition-valued input. The exact instantiation to h_R is proved in goldbach_weighted_mean_from_tenenbaum, with Kmean and delta fixed before R,n,x,epsilon. All applicability requirements, including R<=x^epsilon and6 log R+10K<=epsilon^2 log x, are explicit and verified in the consuming proof. The input contains no Goldbach sequence, h_R, multiplier set, singular integral or paper main term. Its general corollary derivation and remaining external scope are recorded in docs/EXTERNAL_WEIGHTED_MEAN_INPUTS.md. No new Lean axiom or unchecked proof is introduced. Full weighted summation, integration and the final upper comparison remain internal obligations; l:wumatomakisum remains open.

The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. The effective Wirsing theorem and the independent prime logarithmic Mertens facts remain explicit inputs. Their exact application to the actual R-dependent weights is proved. See EXTERNAL_WEIGHTED_MEAN_INPUTS.md. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1234_GoldbachWeightedNormalization.md`

Checkpoint 1234: Exact lower and upper weighted Euler normalizations

Both arithmetic normalizations in the weighted comparison are now exact Lean identities for the original quantities. The lower identity is X_n*Theta_n(z)=3*C_R(n)*Re(H_(1,R)(n))*V_3(R,z), where V_3 is the literal product over R<p<z, p=3 mod4. For ell=2*u*p2, the upper identity is X_n(ell)*Theta_(n,ell)(z_ell)=6*B_R(n)*h_R(u)*Re(H_(ell,R)(n-1))/ell*V_all(R,z_ell). The explicit conditions are R>=3, R<z_ell, 0<u<z_ell<=p2, prime p2 and prime support of u in1 mod4. The actual closed multiplier geometry supplies these conditions once R< N^(2/9).

The proofs partition the actual finite prime sets at the inclusive small-prime cutoff, prove the small divisor equivalence p|ell iff p|u below p2, handle zero arithmetic factors without dividing by them, prove the prime-divisor product identity for h_R(u), and cancel the omitted outer factors exactly. The constants3 and6 are the exact24/phi(24) and24/phi(12), respectively. No asymptotic normalization is assumed. No new external input is used by these identities. The full weighted comparison remains open pending analytic summation, integration and smoothing.

The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. The effective Wirsing and prime Mertens inputs remain as recorded; this checkpoint proves exact arithmetic identities without consuming those inputs. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1235_GoldbachWeightedHarmonic.md`

Checkpoint 1235: Uniform harmonic control and normalized upper mean values

The actual varying weight has a checked uniform harmonic bound: sum_{u<=U}h_R(u)/u<=3*((1+K/log2)*(log(U+1)/log2)^2)^3 for U>=2, independently of n and R. The proof embeds the finite sum in the divisors of floor(U)!, expands the multiplicative divisor sum, bounds geometric prime-power sums, separates5, and uses the existing preliminary interval-product Mertens input. No Shiu conclusion is assumed.

The finite Euler product in the effective mean value is exactly(C_R/B_R) times the ordinary inverse prime product on R<p<=x, p=1 mod4. Consuming standard ordinary/progression Mertens ratios gives sum_{u<=x}h_R(u)<=(kappa+Kmean*epsilon^delta)*(1+Km/log R)*(C_R/B_R)*x/(sqrt(log R)*sqrt(log

x)), with kappa=exp(-gamma/2)/sqrt(pi). Kmean and delta are fixed before R,n,x andepsilon. Every condition of the effective mean-value input is retained and internally checked. The additional ratio input contains only fixed-progression prime products. No own-paper weighted summation or integration endpoint is assumed; l:wumatomakisum remains open.

A staging preflight issue was reconciled before compilation or any save attempt: identical draft copies were verified, and their temporary import/audit entries were removed and restaged after preparing the missing scope. The driver now reads the reviewed scope before staging. The reconciliation is recorded; no earlier proof source was changed.

The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1236_GoldbachWeightedAbel.md`

Checkpoint 1236: Quantitative Abel estimates and exact multiplier parametrization

Two quantitative real Abel estimates and their full model-error identity are kernel checked. One consumes an upper bound for a nonnegative summatory function against a decreasing positive weight, including the exact lower-boundary term. The other compares an increasing positive weighted sum to a differentiable model with bounded cumulative error, with the explicit error2B*f(b). All endpoints, finite floor cutoffs, integrability and integration by parts are proved.

The actual closed multiplier set L is proved to be the image of its finite(u,p2) pairs, and the map(u,p2)->2*u*p2 is injective on this set. Its proof uses the disjoint1 mod4 support of u and3 mod4 prime p2. Hence finite sums over the original L equal sums over the parametrizing pairs, with no multiplicity assumed away. The actual reciprocal weighted pair mass has a uniform logarithmic power7 bound derived from the preceding harmonic theorem and the elementary harmonic sum. No new deep input is used. The full weighted source inequality remains open; the new general Abel facts are proved tools for its internal analytic deduction.

`Checkpoint_1237_GoldbachWeightedKernels.md`

Checkpoint 1237: Kernel calculus, exact W normalization and thin integration window

The rational logarithmic kernels used in both weighted summations have checked derivatives, signs and their precise quotient/log identity. The mean model A*x/sqrt(log x) has its checked derivative and upper density bound. These calculus facts apply on the explicit positive domains needed for Abel summation.

The constant integral is now the literal paper W(alpha), specialized to alpha=9/8. Lean evaluates the inner rational integral by a proved logarithmic primitive, proves its continuous dependence on r, its nonnegativity, and integrability of its r^(-1/2) weighted outer integral. An exact affine substitution proves

I_(9/8)=8*sqrt(2)*W(9/8), including the endpoint r=0, without a numerical approximation. The original displayed W integrand is interval integrable and W(9/8)>=0. The square-root endpoint is handled using the integrable power-1/2, not omitted.

The discarded integration window is also controlled: for n>=4 and0<=T<=n/4, the measure of{y>=2:0<n-1-y^2<T} is at most2T/sqrt(n), with the exact square-root interval inclusion and width proved. No new deep input is used. Weighted Abel applications to the actual coefficient families, two-variable summation, smoothing and final normalization remain before closing l:wumatomakisum.

All 1327 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5120-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4342 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1329 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. Earlier effective Wirsing and prime Mertens inputs retained. All calculus, W normalization and thin-window facts in this checkpoint are internal Lean proofs. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The weighted upper

main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1238_GoldbachWeightedPrimeBalance.md`

Checkpoint 1238: Actual prime and varying-weight Abel applications

The actual primes3 mod4 logarithmic summatory function is now controlled from the independent ordinary and1 mod4 Mertens input. Lean proves the exact prime partition including the prime2 correction, and an absolute discrepancy bound2K+1. Its concrete increasing-kernel Abel application gives the prime weighted integral with the explicit endpoint error2*(2K+1)*g(b), with all derivatives, signs and integrability proved.

The decreasing-kernel application to the actual varying multiplicative weight is also complete. It gives an integral against A/(t*sqrt(log t)) plus the exact lower-boundary term A/(sqrt(log a)*L(a)^2). The theorem goldbach_weighted_mean_abel_effective instantiates this with the normalized effective mean-value theorem: Kmean and delta are chosen once before R,n and every interval. Conditions imposed at the lower interval endpoint propagate to every t in the interval by proved monotonicity of logs and powers. No interval-specific mean-value estimate is assumed. These two quantitative one-variable applications are the inputs to the remaining two-variable summation. The full source weighted comparison stays open; no new external input is introduced.

The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. Existing effective Wirsing and ordinary/progression Mertens inputs retained. No new external input in these concrete Abel applications. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The weighted upper

main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1239_GoldbachWeightedFiniteIntegration.md`

Checkpoint 1239: Finite weighted integration and smoothing identities

Finite integration over variable upper intervals is checked with the original real endpoints and all integrability requirements: a finite sum of integrals over[a,b_i] equals the integral over[a,U] of the corresponding filtered finite sum. The ordinary outer prime products are proved to lie between0 and1. Two finite complex-to-real smoothing inequalities bound the weighted discrepancy by E times the reciprocal weight mass, with the extra outer factors absorbed using their proved[0,1] range.

The original archimedean integrals for every positive multiplier now have their literal real-integrand representation, uniform bounded-integrand integrability, nonnegativity, and the exact finite weighted sum/integral interchange. This includes the actual logarithmic window and the shift n-1; it does not substitute a power model for H_ell. These internally proved integration and smoothing tools will be applied to the quantitative weighted kernel bound. No new external input is used, and no own-paper endpoint has been assumed. The complete weighted comparison remains open until the two-variable estimate and final assembly are discharged.

main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1240_GoldbachWeightedKernelIntegration.md`

Checkpoint 1240: Weighted upper main term: integration and logarithmic geometry

Weighted upper main term: integration and logarithmic geometry

The real Archimedean integrals now reduce to the actual finite weighted logarithmic kernel sum. The comparison uses H_1(n) directly. The discarded region is bounded by 2T/sqrt(n) times the reciprocal weight mass, divided by (log 2)^3. All support restrictions and integrability arguments are proved.

The two changes of variables p=exp(Dv), u=exp(Dr)/2 are checked. They identify the resulting iterated integral with the existing exact integral for 8 sqrt(2) W(9/8). This includes extension to the integrable r=0 endpoint. No numerical or asymptotic estimate is used in that identity.

This checkpoint does not assert the weighted upper main-term lemma. The double finite sum, endpoint errors, small-u contribution, and final uniform comparison remain to be assembled. The independent mean-value and Mertens inputs retain their previously documented scope; no new external input is introduced.

bach conclusion remain open.

`Checkpoint_1241_GoldbachWeightedMeanCutoffs.md`

Checkpoint 1241: Weighted upper main term: small denominators and comparison losses

Weighted upper main term: small denominators and comparison losses

The strongly multiplicative weight now has a uniform coarse mean estimate for x at least R^D, with constants chosen before R and n. A finite Abel argument gives a harmonic tail estimate from a linear summatory bound. Combining this with the already checked finite Euler-product majorant controls all small denominators, including those outside the effective half-dimensional mean range.

Prime reciprocal sums are bounded from the independent logarithmic Mertens input. The factor introduced when replacing log u by log(2u), the retained-region logarithmic loss, and 3 sqrt(alpha) c_alpha = 48 exp(-gamma/2)/sqrt(pi) are checked exactly.

The weighted upper main-term source claim stays open until the finite double sum, integration, and uniform relative errors have all been assembled. No new external input is introduced and the selected manuscript is unchanged.

Checkpoint notes 1242-1265

Checkpoint_1242_GoldbachWeightedSmoothing.md

Checkpoint 1242: Weighted upper main term: source normalization and finite smoothing error

Weighted upper main term: the source sum and smoothing error

The actual source sum over multipliers is now exactly normalized as a finite sum over the unique pairs (u,p), with the concrete B_R, h_R, Euler factors, and smoothed singular integrals. The geometric bounds place every pair in the required sieve range. Applying the existing uniform smoothing theorem gives an explicit total error bounded by 6 B_R K N/sqrt(R) times the actual reciprocal weight mass.

A separate finite fiber argument bounds the weighted pair sum by the explicit prime-by-denominator rectangle. It preserves the p=z endpoint and the inclusive upper floor. The proof includes the coverage of the actual source pairs and all nonnegativity needed to enlarge the summation domain.

The weighted upper main-term source claim remains open pending the sharp double-sum bound and uniform error assembly. No new deep input is used, and no manuscript edits are applied.

Checkpoint_1243_GoldbachWeightedPrimeEndpoints.md

Checkpoint 1243: Weighted upper main term: two Abel estimates and prime endpoints

Weighted upper main term: two Abel estimates and prime endpoints

The prime-kernel estimate now applies to an arbitrary finite set of primes in the closed interval [z,b]. The possible prime at z contributes at most 1/(z (log z)^2); the logarithmic Mertens error contributes at most 2(2K+1)/(log z)^3. Thus the inclusive source convention is respected.

The actual strongly multiplicative denominator weight has a two-variable Abel reduction. Its finite sum is bounded by the integral of the remaining prime kernel plus an explicit summatory boundary term. The proof checks continuous integrability on the full rectangle, interchanges the finite variable intervals exactly, and retains the uniform mean hypothesis with its existing independent provenance.

The weighted upper main-term claim remains open until the integral estimate and all uniform relative errors are assembled. No new external input or manuscript modification is introduced.

`Checkpoint_1244_GoldbachWeightedDoubleGeometry.md`

Checkpoint 1244: Weighted upper main term: logarithmic region and sharp integral

Weighted upper main term: the double-integral region

The logarithmic region for the two summation orders is checked: u <= exp(D)/(2p^2) is equivalent to p <= exp((D-log(2u))/2). Its bounds imply all derivative signs and nonvanishing denominators needed by the two Abel estimates.

The resulting integral is bounded sharply by sqrt(1+log(2)/log(a)) sqrt(D) 8 sqrt(2) W(9/8). The factor records the replacement of log(u) by log(2u) and tends to one at the intended cutoff. A separate explicit integral bound controls the prime endpoint and Mertens errors.

These are internal proved analytic steps. The independent mean-value and Mertens boundaries are unchanged. The source upper main-term comparison is still open pending finite assembly and uniform relative error estimates.

`Checkpoint_1245_GoldbachWeightedLargeRectangle.md`

Checkpoint 1245: Weighted upper main term: sharp finite double sum and cutoff split

Weighted upper main term: sharp finite rectangle estimate

The two checked Abel estimates and the checked logarithmic changes of variables now give the finite large-denominator estimate. Its leading coefficient is the exact paper integral W(9/8). Prime endpoints, logarithmic Mertens errors, and the summatory boundary are explicit additional terms.

The actual source pair kernel is split at a real cutoff a. The small-denominator part is bounded by its weighted harmonic sum and a prime reciprocal sum. The large part is placed in the active rectangle, with the actual floors and logarithmic denominators preserved. All enlargements use proved nonnegative weights.

No error term is silently discarded. The source comparison remains open until these explicit terms are shown to be uniformly negligible and inserted into the source main-term normalization. No new external theorem is assumed.

`Checkpoint_1246_GoldbachWeightedFiniteKernel.md`

Checkpoint 1246: Weighted upper main term: actual finite kernel and scale limits

Weighted upper main term: quantitative source kernel and scale limits

The source pair kernel now has one checked quantitative upper bound. Its inputs are the internally proved summatory and harmonic estimates; its output retains the exact W(9/8) term and all prime, floor, and boundary errors. The estimate concerns the actual pair sum, with no abstract replacement of the paper's main term.

The logarithmic scale limits are proved separately: the leading coefficient tends to the half-dimensional constant times W, and the small-denominator and prime endpoint coefficients tend to zero. These results use the pinned Mathlib asymptotic lemmas and explicit inequalities.

The final weighted upper main-term lemma still requires the uniform cutoff budgets, moving-logarithm comparison, and insertion into the normalized source singular integrals. No new external input is introduced.

Checkpoint 1247: Weighted upper main term: uniform cutoffs and scalar errors

Weighted upper main term: error absorption and valid cutoffs

The finite-kernel prime errors and Abel boundaries have explicit scalar majorants with the correct vanishing scale. The leading scalar identity preserves the exact W coefficient.

For R=(log N)^C and a=exp(sqrt(log N)), all hypotheses of the effective mean estimate are eventually valid: the lower scale, the prime-balance budget, the epsilon range, and the overlap with the coarse mean bound. These statements choose thresholds independently of n.

The small-denominator harmonic sum is bounded by (C_R/B_R) times a fixed constant times (log R)^6 plus the coarse mean tail. This retains all arithmetic dependence explicitly. The final weighted source comparison remains open until the uniform kernel and singular-integral assembly are complete.

<!-- checkpoint-verification -->

Verification

All 1348 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5141-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4405 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1350 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 remains open. Previously documented independent mean-value/Mertens inputs only. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

Checkpoint_1248_GoldbachWeightedKernelCoefficient.md

Checkpoint 1248: Weighted upper main term: effective source kernel and coefficient

Weighted upper main term: effective arithmetic kernel

The actual finite kernel bound is now instantiated with the concrete strongly multiplicative mean and harmonic estimates. Its constants are chosen before the cutoff exponent, scale, and target integer. All remaining hypotheses are explicit scalar cutoff inequalities whose eventual validity has been proved.

The coefficient is normalized by (C_R/B_R)/(sqrt(log R) log(N) sqrt(log N)). Its exact factorization is checked, and its limit is (exp(-gamma/2)/sqrt(pi)+K epsilon^delta) W(9/8). The small-denominator and endpoint components tend to zero independently of n.

This is a complete effective kernel implication from the documented independent inputs. The original weighted main-term claim remains open pending the sharp eventual moving-kernel estimate and its singular-integral and relative-error assembly. No new external endpoint is assumed.

The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1249_GoldbachWeightedKernelUniform.md`

Checkpoint 1249: Weighted upper main term: sharp uniform moving kernel complete

Weighted upper main term: sharp uniform kernel estimate

The weighted kernel estimate is complete in epsilon form. For every fixed positive cutoff exponent C and every eta>0, the actual finite source pair kernel is eventually bounded by (kappa W(9/8)+eta)(C_R/B_R)/(sqrt(log R) log N sqrt(log N)), uniformly in n.

The same sharp bound holds for every m between N^2(log N)^(-A) and N^2. The proof controls the moving logarithmic denominator, respects its support filter, and chooses a positive tolerance using a checked continuity argument. All effective mean hypotheses are discharged by the proved cutoff budgets; no paper-specific estimate remains among the independent inputs.

The full source main-term claim still requires insertion into the singular integrals, total smoothing and discarded-region errors, and comparison with the lower main term. The existing independent mean-value and Mertens assumptions are unchanged.

`Checkpoint_1250_GoldbachWeightedMass.md`

Checkpoint 1250: Weighted upper main term: source outer products and total mass

Weighted upper main term: source normalization and total error mass

The actual reciprocal mass over source pairs is bounded uniformly by a fixed constant times (log N)^7. The proof starts from the checked finite harmonic product estimate.

The original upper main-term sum is bounded by 24 B_R (1+K/log R) log R times the weighted Archimedean sum, plus its explicit total smoothing error. The lower main term is bounded below by 3 sqrt(9/8) (1-epsilon)^2 times the common reference C_R H_1(n) sqrt(log R/log N), whenever the two elementary relative error conditions hold.

Both results use the source's actual Euler products and singular integrals. The exact constant identity and arithmetic factors are preserved. The weighted upper comparison remains open pending the uniform relative errors and final assembly.

The weighted upper main-term sum, upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1251_GoldbachWeightedErrorBounds.md`

Checkpoint 1251: Weighted upper main term: all uniform relative errors

Weighted upper main term: uniform relative errors

Both errors are now bounded relative to the common positive reference C_R H_1(n) sqrt(log R/log N), using the actual retained range for n. With the truncation exponent A+14 and C >= A+24, the discarded-region error is bounded by a fixed multiple of (log N)^(-3), and the total smoothing error by a fixed multiple of (log N)^(-2), times that reference.

The lower singular integral has relative smoothing error at most 8K/log N. All scale restrictions, Mertens error tolerances, positive truncation heights, and the R-to-power-of-N comparisons are eventually valid with thresholds independent of n.

No paper-specific asymptotic error is assumed. These are proved inequalities and limits. The source weighted upper main-term lemma remains open only until the final checked assembly is staged.

`Checkpoint_1252_GoldbachWeightedSourceBridge.md`

Checkpoint 1252: Weighted upper main-term comparison complete

Weighted upper main term: complete conditional formalization

The source lemma **l:wumatomakisum** is complete in uniform epsilon form. Its checked endpoint is `goldbach_weighted_upper_main_term_complete` in `PrimeSquares/GoldbachWeightedUpperMainTerm.lean`.

For every A>0, every fixed C>=A+24, and every eta>0, one threshold in N works for every n=12 modulo24 with N^2(log N)^(-A)<=n<N^2. With R=(log N)^C and alpha=9/8, the actual source sum satisfies

$$\sum_{\ell\in L} X_n(\ell)\Theta_{n,\ell}(z_\ell) \le (c_\alpha \mathcal{W}(\alpha)+\eta)X_n\Theta_n(z), \qquad c_\alpha=\frac{16e^{-\gamma/2}}{\sqrt{\pi\alpha}}.$$

This is the source uniform o(1) statement. The original main terms, multiplier set, local factors, Euler products and singular integrals are used. No paper conclusion is an external hypothesis.

The proved chain includes the arithmetic cancellation, strong multiplicativity and uniform prime-balance application, the small-denominator estimate, both finite Abel arguments, the prime endpoint p=z, the exact W integral, the sharp fixed and moving kernel, finite integration, total smoothing error, the discarded region, and the final positive lower comparison. A=the retained-range exponent, A+14 is a sufficient integration cutoff exponent, and C>=A+24 suffices for all error estimates.

The explicit independent hypotheses are the generic effective half-dimensional mean-value corollary of the corrected Tenenbaum theorem, ordinary/fixed-progression logarithmic Mertens estimates, the three ordinary relative Euler-product estimates, and the previously recorded interval-product Mertens bound. Their precise general interfaces and unformalized classical corollary reductions are in `docs/EXTERNAL_WEIGHTED_MEAN_INPUTS.md`. They are theorem parameters, not new Lean axioms. The entire weighted source application is proved. This milestone does not require a new Goldbach, weighted-prime-counting, or Siegel-Walfisz endpoint as an assumption.

The accompanying full build, source audit and exact axiom audit must pass before this checkpoint can be saved by the checkpoint driver. The selected manuscript and all accepted source hashes remain unchanged. The claim ledger moves from29 to30 completed conditional implications, leaving4 open entries: the upper sieve, numerical comparison, final Goldbach theorem, and the original weaker pre-sieving statement awaiting source synchronization. The latter is bookkeeping about the manuscript; its corrected stronger variant is already formalized.

Files and continuation

The complete project is in the checkpoint ZIP, including the pinned Lean/Mathlib configuration, all earlier proofs, verification records and recovery instructions. `blueprint/Weighted_Upper_Main_Term_Complete.md` presents the complete mathematical proof by topic. The next substantive milestone is the full upper-sieve application `p:sieveneedupper8`.

Suggested paper replacements

The lemma statement and constant need no change. The following two proof edits are saved in `docs/WEIGHTED_UPPER_MAIN_TERM_REPLACEMENTS.tex`; they have not been applied to the selected manuscript.

1. In Step1, replace the passage beginning “Finally, since $p_2 > z$ and $\ell = 2up_2 \ge p_2$, we have” through “all sufficiently large N” with:

```
Finally, since \(p_2\geq z\) and \(\ell=2up_2\geq p_2\), we have
\[
 z_\ell
 =\left(\frac{N^2}{\ell}\right)^{1/4}
 \leq\left(\frac{N^2}{p_2}\right)^{1/4}
 \leq\left(\frac{N^2}{z}\right)^{1/4}
 =N^{5/18}<N^{8/9}=z.
\]
Thus \(p_2\geq z>z_\ell\), and, since \(R=(\log N)^C\), also
\(p_2>R\) for all sufficiently large \(N\).
```

This preserves the inclusive endpoint in the definition of L.

2. In Step6, replace “Applying (`e:Wsum10`) on the remaining range gives” through “Therefore”, immediately before the existing display labelled `e:integratedW10`, with:

```
On the retained range \(m(y)\geq N^2(\log N)^{-A_1}\), we have
\(\log m(y)=(2+o(1))\log N\). Applying \eqref{e:Wsum10} therefore gives
\[
 \sum_{\substack{\ell=2up_2\in L\\2\ell\leq m(y)}}
 \frac{h_R(u)}{\ell(\log(m(y)/\ell))^2}
 \leq
 \left(\frac{e^{-\gamma/2}}{\sqrt\pi}\mathcal W(\alpha)+o(1)\right)
 \frac{C_R(n)}{B_R(n)}
 \frac{1}{\sqrt{\log R}(\log N)^{3/2}}.
\]
For these \(y\), we also have \(2\leq n-y^2\leq N^2\), so
\((\log y)^{-1}\leq
2\log N/(\log y\log(n-y^2))\).
The indicator in the definition of \(H_1(n)\) equals one on this range.
Integrating the preceding bound, and including the already estimated
 discarded region, gives the following inequality. For the latter error,
use \(C_R(n)/B_R(n)\geq1\) and \eqref{e:H1elementary10}, choosing
\(A_1\) sufficiently large in terms of \(A_0\).
```

Keep the existing `e:integratedW10` display unchanged. Equality at finitely many boundary points does not change the integrals. This edit retains the cutoff where the real logarithmic powers are valid and compares directly with H_1(n), without a separate shift asymptotic.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough

full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 is complete through the weighted main-term comparison; the upper sieve and final Goldbach deductions remain open. Independent general effective mean-value and classical Mertens hypotheses remain explicit and unproved; all own weighted upper main-term deductions are complete. Earlier independent theorem scopes are unchanged. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The full weighted upper main-term comparison l:wumatomakisum is a complete checked implication from the documented independent effective mean-value and Mertens inputs, with the exact printed constant and uniform retained-range quantifiers. The upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1253_GoldbachSieveNumericalComparison.md`

Checkpoint 1253: Exact normalized sieve comparison

The source numerical comparison l:numericalcomparison is complete conditional only on the classical normalization of the independent sieve functions. Lean proves 8 sqrt(2) W(9/8)<=9/32 by bounding the actual inner integrand, integrating the two real powers exactly, and using the previously checked W change of variables. It then proves c_(9/8) exp(gamma) W(9/8)<=3 exp(gamma/2)/(8 sqrt(pi)), whereas the lower coefficient is (2 sqrt(2)/3) log(2) exp(gamma/2)/sqrt(pi). The elementary exact inequality log(2)>=1/2 already makes the difference strictly positive. This proves more than a floating-point calculation: every integral comparison and algebraic inequality is kernel checked. The printed weaker W bound remains valid. No new manuscript correction is needed here. The existing decimal claim >0.17 is not used or credited by this checkpoint; the required strict positivity is proved.

The generic functions in the independent sieve interfaces retain explicit normalization identities at9/8 and2. These identities belong to the classical general sieve boundary (Iwaniec1980,(1.8)-(1.10)); they are not a paper conclusion or an added Lean axiom. A source retrieval attempt identified the publisher DOI10.4064/aa-36-2-171-202 but its PDF hosts denied access in this run; the formal theorem transparently retains both normalization identities as hypotheses.

The upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1254_GoldbachUpperSieveDensity.md`

Checkpoint 1254: Upper-sieve densities and uniform level geometry

The upper sieve now has the exact density and scale prerequisites. Its preliminary dimension2 includes the exceptional prime5 with barrier1/2; its outer dimension1 follows from an explicitly independent all-prime interval Mertens input. The new interface contains only finite products over arbitrary prime subsets and no Goldbach sequence, local roots, main terms or paper conclusions. It is the all-prime counterpart of the already documented interval Mertens boundary.

For every fixed B>=0 and C, the actual levels z_ell=(N^2/ell)^(1/4) and D_ell=sqrt(N^2/ell)/(12(log N)^B) satisfy R+1<=z_ell<=D_ell/D0<=N^2 eventually, uniformly for1<=ell<=N^(10/9). The exact logarithmic identity proves log(D_ell/D0)/log z_ell tends to2 along every admissible varying multiplier path. The eventual uniformization and source application are next. No own-paper endpoint has been assumed.

`Checkpoint_1255_GoldbachUpperPresieveUniform.md`

Checkpoint 1255: Uniform upper presieve and exact sequence bridge

The complete upper presieve prerequisite is now uniform over all1<=ell<=N^(10/9), with the actual levels and the coefficient quantifier preceding every density and sequence. A general filter selection proof derives uniformity from all admissible multiplier paths; the exact level geometry makes the classical two-stage input applicable along every such path. Continuity of the independent normalized F_1 at2 yields one common tolerance.

The actual source progression residue is selected independently of n, with a coprime fallback for irrelevant moduli. Lean proves the exact cardinality identity with the actual upper density, actual main term and shifted full circle remainder at n-1. Nonnegativity of the upper main term, including vanishing arithmetic factors, is established from the exact product and positive singular integral. No new independent input is added. The finite source sieve application, coefficient embedding and summed remainder are next.

Verification

All 1363 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5156-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4450 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1365 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input

includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 is complete through the weighted main-term comparison; the upper sieve and final Goldbach deductions remain open. Independent general effective mean-value and classical Mertens hypotheses remain explicit and unproved; all own weighted upper main-term deductions are complete. Earlier independent theorem scopes are unchanged. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The full weighted upper main-term comparison l:wumatomakisum is a complete checked implication from the documented independent effective mean-value and Mertens inputs, with the exact printed constant and uniform retained-range quantifiers. The upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1256_GoldbachUpperPresieveApplication.md`

Checkpoint 1256: Actual upper sieve and summed error estimates

The actual source upper sieve is assembled at each multiplier, including the vanishing arithmetic-factor case, and summed over the corrected closed multiplier set. All coefficients have absolute value at most1 and are chosen before n. The original double sum of remainders is embedded injectively into the circle-method coefficient family with L0=N^(6/5) and delta=3/4. The shift n-1, the factor12, strict divisor levels and all coprime residue requirements are checked. The complete shifted mean square is bounded by2M N^4(log N)^(-A).

The fixed-sieve comparison uses exactly the previously proved K N^(1/4) correction. Adding it to the summed remainder yields a mean square at most(4M+2K^2)N^4(log N)^(-A), for large N. The proof conservatively bounds its squared total by O(N^3), which is sufficient for every logarithmic saving.

A new record collects only the previously explicit independent classical inputs and normalizations; it contains no manuscript endpoint. The exact numerical gap follows from these general normalized values. The final upper coefficient assembly and common-cutoff lower/upper closure are next. No new deep input is added.

Verification

All 1368 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5161-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before

reuse; new/changed modules and the root are compiled. All 4459 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1370 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 is complete through the weighted main-term comparison; the upper sieve and final Goldbach deductions remain open. Independent general effective mean-value and classical Mertens hypotheses remain explicit and unproved; all own weighted upper main-term deductions are complete. Earlier independent theorem scopes are unchanged. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The full weighted upper main-term comparison l:wumatomakisum is a complete checked implication from the documented independent effective mean-value and Mertens inputs, with the exact printed constant and uniform retained-range quantifiers. The upper sieve, numerical comparison and final Goldbach conclusion remain open.

`Checkpoint_1257_GoldbachUpperSieveComplete.md`

Checkpoint 1257: Full upper-sieve proposition complete

The full source proposition p:sieveneedupper8 is complete. For every A0>0 and desired logarithmic mean-square saving A>0, a single B and C>=A0+24 is chosen before the tolerance. For every eta>0 and all large N, coefficients independent of n give the actual upper count at most(c_(9/8) F_1(2) W(9/8)+eta) X_n Theta_n(z)+E2(n), uniformly for retained admissible n. The actual E2 is the checked shifted double remainder plus the fixed-sieve K N^(1/4) correction; its full mean square is O(N^4(log N)^(-A)). No source main term, prime-counting weight or sieve endpoint is a hypothesis.

The checked theorem uses the explicit independent general input record described in docs/SECTION_11_UPPER_SIEVE_INPUTS.md. It includes the general sieve-function normalization and continuity, general one-stage sieve theorems, ordinary Mertens estimates and the effective mean-value theorem; their proofs remain external in the agreed scope.

The lower analytic theorem is now exported for every fixed B,C, and its exact mean-square remainder can be transported from the same circle bound as the upper remainder. This removes a possible mismatch between separately existential cutoff choices. The final common-cutoff Section11 theorem is next. The literal weaker presieving manuscript statement still requires its saved hypothesis replacements; no unsupported source claim is silently promoted.

The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; Section11 lower, weighted-upper and full upper-sieve estimates and normalized numerical positivity are complete conditional implications; the final Goldbach assembly and manuscript presieving synchronization remain. Independent general effective mean-value and classical Mertens hypotheses remain explicit and unproved; all own weighted upper main-term deductions are complete. Earlier independent theorem scopes are unchanged. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The full weighted upper main-term comparison l:wumatomakisum is a complete checked implication from the documented independent effective mean-value and Mertens inputs, with the exact printed constant and uniform retained-range quantifiers. The complete upper-sieve proposition and strict numerical comparison are proved conditionally with exact constants and uniform quantifiers. The final Goldbach assembly and manuscript presieving synchronization remain.

`Checkpoint_1258_GoldbachSection11Complete.md`

Checkpoint 1258: Section11 complete at one shared cutoff

Section11 is complete for the reviewed corrected statements. The joint endpoint goldbach_section11_complete uses one B,C for the actual lower and upper sieve counts, actual common main term, the lower bound k N(log N)^(-(A0/2+6)), and both original remainder families. It gives the exact lower coefficient f_(1/2)(9/8), the exact upper coefficient c_(9/8) F_1(2) W(9/8), uniform tolerances, coefficients chosen before n and a combined mean-square saving of arbitrary logarithmic order. C can exceed any prescribed minimum and C>=A0+24 is sufficient. The exponent A0/2+6 is independent of C. Strict positivity of the normalized coefficient difference is already kernel checked.

The general one-stage sieve, SW/BV, Ren/Ghosh, effective multiplicative mean and classical Mertens inputs, plus classical sieve-function continuity and normalization, remain explicit independent hypotheses. No paper endpoint is an input or an added mathematical axiom.

A complete replacement copy is saved as sources/review/Section11_Reconciled.tex. It applies the earlier presieving hypotheses and endpoint correction, both lower-bound notation fixes, the weighted integration correction, the inclusive p2=z endpoint in both occurrences, and a shorter exact numerical-comparison proof matching Lean. Original manuscript files and their accepted hashes remain unchanged. The generated copy has unique labels and balanced environment counts; it has not been typeset as a standalone document. The reproduction script and exact replace-with manifest are included.

Crucial source distinction: the weaker original l:presieving hypothesis is not claimed proved. Its completed claim now points explicitly to the separately supplied corrected statement, whose bytes and original-statement bytes are guarded by hashes. The user manuscript still requires those edits. This review-copy completion does not assert that the user has applied them. The remaining open paper-level claim is the final quantitative Goldbach theorem; the original presieving version is retained as a superseded, unclaimed variant.

The weighted endpoint uses the checked effective upper-mean route. It does not add completion credit to

every stronger asymptotic displayed in the manuscript's alternative convolution argument. The exported lemma conclusions and the joint sieve estimates are what is certified.

The latest upload and selected reconciled copy are preserved. The Section9 arithmetic/final-count reductions are checked for the user-corrected closed L; all Section10 statements and the full circle-method implication are complete in the agreed conditional scope; All Section11 theorem statements, using the explicitly supplied corrected presieving replacement, are complete in the agreed conditional scope. The common-cutoff lower/upper assembly, exact constants and complete error estimates are proved; the original manuscript still needs the supplied replacements. Independent general effective mean-value and classical Mertens hypotheses remain explicit and unproved; all own weighted upper main-term deductions are complete. Earlier independent theorem scopes are unchanged. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The full weighted upper main-term comparison l:wumatomakisum is a complete checked implication from the documented independent effective mean-value and Mertens inputs, with the exact printed constant and uniform retained-range quantifiers. The complete upper-sieve proposition and strict numerical comparison are proved conditionally with exact constants and uniform quantifiers. The joint Section11 estimates are proved at one cutoff. The final Goldbach theorem is the next assembly; the supplied presieving replacement still needs to be copied into the user manuscript.

`Checkpoint_1259_GoldbachQuantitativeExceptionalSet.md`

Checkpoint 1259: Section11 and quantitative Goldbach theorem complete

Section11 is complete in the agreed conditional scope, and the final quantitative Goldbach theorem has also been assembled. The endpoint goldbach_headline_theorem proves, for every A>0 and all sufficiently large real X, the actual exceptional-set bound |E2(X)|<=D_A X(log X)^(-A).

The definition is matched exactly to positive n<X congruent12 mod24 with no representation a^2+b^2+p^2+1=n in which p and a^2+b^2+1 are prime and a,b are coprime. The finite prime representation, primitive sum-of-two-squares predicate and exceptional-set membership equivalence are proved. The common-cutoff Section11 theorem supplies both sieves, the lower main-term exponent A0/2+6 independent of C, exact normalized sieve constants and arbitrary combined logarithmic mean-square saving. The positive numerical gap, threshold choice, divisor-error absorption, Chebyshev step and small-n contribution are all discharged. Finally N=ceil(sqrt(X)), X<=N^2<=4X and log N>=log X/2 transfer the square-cutoff estimate to every real X with the explicit factor4*2^A.

The upper-sieve proposition is complete with the exact coefficient c_(9/8) F_1(2) W(9/8), coefficients chosen before n and the actual shifted double remainder. Its full mean square, including the fixed-sieve O(N^(1/4)) comparison, has arbitrary logarithmic saving. The rational integral proof gives8 sqrt(2) W(9/8)<=9/32 and proves strict positivity without floating point or an unchecked evaluator.

Independent hypotheses remain explicit: raw SW and BV, Ren/Ghosh, the general one-stage sieve theorems and their normalized values/continuity, the general effective multiplicative mean corollary, classical ordinary/progression Mertens estimates, and the primitive two-square criterion. Previously recorded independent inputs for earlier sections retain their scopes. These are theorem parameters, not added Lean axioms. No source sieve, weighted main term, numerical comparison or Goldbach endpoint is postulated.

The full replacement copy sources/review/Section11_Reconciled.tex is included, together with a reproducible reconciliation script and a manifest of exact replace-with passages. It includes the required strengthened presieving hypotheses and endpoint, the two lower-bound notation corrections, both inclusive p2=z endpoint occurrences, the retained-range integration correction and the exact numerical proof. Original manuscript files and all accepted hashes are unchanged. The corrected statement is the formal target; the literal weaker original presieving statement is not claimed proved and still needs replacement in the user manuscript. No user edit is assumed. The replacement copy has unique labels and balanced environments; no standalone LaTeX typesetting is claimed.

The claim ledger now has19 proved,34 complete conditional implications and1 quoted external theorem, with no remaining internal endpoint among the54 reviewed numbered targets. Presieving credit explicitly points to the corrected review copy with both old/new statement hashes retained. This does not claim to formalize every stronger unnumbered assertion in alternative proofs: the weighted main-term endpoint uses the checked effective-upper-mean route rather than the full convolution asymptotic printed in an alternate derivation. The independent external proofs remain future library work.

Checkpoint1258 already separately saved the full common-cutoff Section11 theorem. This checkpoint additionally closes the final Goldbach theorem and saves every earlier proof and validation record.

The full weighted upper main-term comparison l:wumatomakisum is a complete checked implication from the documented independent effective mean-value and Mertens inputs, with the exact printed constant and uniform retained-range quantifiers. The complete upper-sieve proposition and strict numerical comparison are proved conditionally with exact constants and uniform quantifiers. The joint Section11 estimates are proved at one cutoff. The full quantitative Goldbach theorem is proved conditionally at every large real cutoff X; the supplied presieving replacement still needs to be copied into the user manuscript.

`Checkpoint_1260_GoldbachPrimitiveProducts.md`

Checkpoint 1260: Primitive two-square multiplication without an extra assumption

Recovered and authenticated checkpoint1259. The Section9 statement map was stale even though the curated current ledger already recorded the completed circle-method, both sieves, main-term size, numerical gap and final real-X exceptional-set theorem. This task audits the source section and seeks to remove the remaining elementary PrimitiveTwoSquaresCriterion hypothesis rather than manufacture another proof of already completed counting deductions.

Lean proves seven new arithmetic theorems. A prime-norm sum of squares has coprime coordinates. A common prime divisor of coordinates after multiplication can only be the determinant prime. At an odd split prime, the two conjugate orientations cannot both create that common divisor. Consequently primitive sums of two squares remain primitively represented after multiplication by every prime congruent1 mod4, including repeated prime factors. Integer coordinate signs are handled by natural absolute values, with exact norm preservation.

The only newly imported library result is the already proved Mathlib Fermat two-square theorem, Mathlib.NumberTheory.SumTwoSquares, at the unchanged pinned revision. Its1988-job dependency target was built successfully. No new unproved mathematical input is introduced. The general primitive criterion is not claimed complete until the next stage. Original manuscripts remain unchanged; the user says the edits are in progress, not finished.

The full quantitative Goldbach theorem is proved conditionally at every large real cutoff X; the supplied presieving replacement still needs to be copied into the user manuscript.

`Checkpoint_1261_GoldbachPrimitiveCriterion.md`

Checkpoint 1261: Primitive criterion and remaining Section9 prerequisites proved

The full primitive sum-of-two-squares criterion used in Section9 is now proved unconditionally: for n=2 mod4, n has a coprime sum-of-two-squares representation exactly when no prime3 mod4 divides n. The proof constructs a primitive representation of the odd cofactor using the checked prime-multiplication argument, then doubles it; parity excludes a common factor2. The converse uses Mathlib's already proved obstruction to -1 being a square modulo a3 mod4 prime. No external arithmetic criterion is assumed.

The source's unnumbered assertion that W(alpha) is finite for every alpha>1 is now proved across its full range, with interval integrability of the actual logarithmic kernel. The endpoint square-root singularity is handled by an integrable negative half power; nonnegativity is also proved for the complete range. This extends the earlier special-value formalization at alpha9/8.

A concrete smooth bump with inner radius1/32 and outer radius1/16 is converted to a Schwartz function. Lean verifies value1 at0, nonzero, compact support contained in(-1/8,1/8), and the source support cutoff. Thus the proof will no longer need an externally supplied test function at the final endpoint. No additional source replacement is required for these valid mathematical statements.

This checkpoint saves these prerequisite proofs separately. The next checked export specializes the legacy parameterized Section9 deductions with the proved criterion and fixed seed, and updates the source map. No source claim is promoted before that final statement review. The previously supplied manuscript edits remain in progress; no changed user source is assumed.

`Checkpoint_1262_GoldbachSectionNineComplete.md`

Checkpoint 1262: Section9 complete with the arithmetic criterion proved

Section9 has been reviewed against the actual source, not merely its stale planning map. Its nine numbered statements and the final quantitative exceptional-set theorem all have complete matched formal evidence. The final theorem already followed conditionally at1259; this task removes the remaining elementary arithmetic and seed hypotheses and closes additional source prerequisites.

The primitive sum-of-two-squares criterion is now proved from pinned Mathlib and project algebra. For n=2 mod4, a coprime sum-of-two-squares representation exists exactly when no3 mod4 prime divides n. The proof covers arbitrary prime powers by choosing a conjugate orientation at each split prime, and treats the single factor2 using parity. Consequently l:fromsiftedtop, l:truncationT and c:mastersievereduction are promoted from conditional to proved under their ordinary source hypotheses. The upper arithmetic reduction was already proved. Their actual finite sets, prime-factor multiplicities, closed cutoff and uniform error terms are retained.

The complete source arithmetic exports are goldbach_from_sifted_to_primes_complete, goldbach_truncation_complete, goldbach_section9_master_exact and goldbach_master_sieve_complete. No primitive criterion is a hypothesis. The source assertion that W(alpha) is finite for every alpha>1

is now proved over its full range, including the square-root endpoint singularity; nonnegativity is also proved.

A concrete compactly supported smooth function is constructed with value1 at0 and support inside(-1/8,1/8). The final export goldbach_section9_headline_complete therefore takes only GoldbachSection11Inputs and A>0, and yields the actual real-X exceptional-set estimate. It needs neither a supplied primitive criterion nor a supplied smoothing function. The almost-all statement is also exported as goldbach_section9_exceptional_density_zero.

The circle-method approximation, lower and upper sieve propositions, uniform main-term lower bound and strict numerical gap retain their complete checked conditional scopes. Remaining independent inputs are SW/BV, Ren/Ghosh, the general one-stage sieve and classical sieve normalizations/continuity, the effective multiplicative mean and classical Mertens estimates. None is a paper endpoint. The primitive criterion has been removed from every current claim's external-input list and is explicitly recorded as a proved internal arithmetic lemma.

The Section9 map is reconciled to the actual current nine source statements and their current theorem evidence, replacing the stale1085/1136 planning statuses. The old map is archived. Original manuscript and accepted source hashes remain unchanged. The user is applying the previously supplied Section11 edits; their application is not presumed. No additional Section9 LaTeX replacement was needed. The previously supplied presieving replacement remains the explicitly reviewed target.

The paper ledger now records22 proved under ordinary hypotheses,31 complete conditional implications and1 quoted external theorem among54 reviewed numbered targets, plus4 definitions. This is a statement inventory, not a percentage based on supporting theorem counts. Earlier stronger unnumbered assertions in alternative proof routes retain their separately documented scope; no new completion credit is awarded to them.

Checkpoint1260 separately saved the primitive multiplication proof, and1261 separately saved the complete criterion, general W integral and fixed smooth seed. This checkpoint saves their final Section9 consumption and source reconciliation.

Verification

All 1379 project modules are covered by the authenticated compilation history, beginning with a fresh full build. This checkpoint passes a 5176-job dependency-aware build with remote project artifact reuse disabled. Unchanged earlier proof sources and compiled Lean artifacts are SHA256 checked before reuse; new/changed modules and the root are compiled. All 4494 named theorems pass a fresh complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound; all 1381 Lean files pass the source scan. No placeholders, added mathematical axioms or unchecked evaluation are used. Build receipts record exactly which modules were compiled at every step.

All reviewed current-paper statements in Sections3–8 are complete under their normal hypotheses or as complete implications from explicit independent general inputs. The corrected prime-square input includes one fixed-level Page datum per N, the full extended major range and the sufficient complementary minor estimate. The broad quantitative IW proposition includes the exact real-Q construction, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and finite-dimensional Shannon sampling for every1<=p<=infinity. The general Page/progression, Ren/Ghosh, Tao and other previously recorded independent theorems and their explicit bridges remain unproved. No own-paper endpoint is a new external assumption. The latest upload and selected reconciled copy are preserved. All Section9 arithmetic reductions are proved for the adopted closed L without an extra primitive two-square hypothesis. The full real-X Goldbach estimate and exceptional-density limit follow from the documented independent analytic inputs, with the smooth seed constructed internally; all Section10 statements and

the full circle-method implication are complete in the agreed conditional scope; All Section11 theorem statements, using the explicitly supplied corrected presieving replacement, are complete in the agreed conditional scope. The common-cutoff lower/upper assembly, exact constants and complete error estimates are proved; the original manuscript still needs the supplied replacements. Independent general effective mean-value and classical Mertens hypotheses remain explicit and unproved; all own weighted upper main-term deductions are complete. Earlier independent theorem scopes are unchanged. The full Section11 lower-sieve proposition p:sieveneedlower8 is a complete conditional implication, including its actual main term, uniform o(1), n-independent coefficients and mean-square error. The uniform main-term lower bound l:maintermsize8 and its joint application with the same large cutoff C are also complete conditionally. The full weighted upper main-term comparison l:wumatomakisum is a complete checked implication from the documented independent effective mean-value and Mertens inputs, with the exact printed constant and uniform retained-range quantifiers. The complete upper-sieve proposition and strict numerical comparison are proved conditionally with exact constants and uniform quantifiers. The joint Section11 estimates are proved at one cutoff. The full quantitative Goldbach theorem is proved conditionally at every large real cutoff X; the supplied presieving replacement still needs to be copied into the user manuscript. Section9 also includes a proved full primitive two-square criterion and convergence of W(alpha) for every alpha>1. The old parameterized theorems remain for compatibility; the current matched exports remove those discharged parameters. The user is applying manuscript edits and their application has not been verified against a new upload.

`Checkpoint_1263_FiniteSignedMaximalProof.md`

Checkpoint 1263: General finite signed maximal inequality proved

The general finite signed-sum maximal inequality is now proved without an independent analytic hypothesis. For any finite sequence of complex functions on the integers and every exponent at least one, a uniform Lp bound B for all sums with scalar coefficients of modulus at most one gives an Lp bound (ceil(log2 J)+1) B for the largest initial partial sum. The checked depth comparison gives the explicit bound 6 log(2+J) B. This proves the exact existing RawFiniteSignedMaximalInput interface at constant 6, including J=0, Lp membership, and extended-real B.

The proof uses exact finite Boolean-sign orthogonality and reconstruction. Each coordinate is dominated by the finite average of the norms of all signed sums. Minkowski then bounds the largest block at each level, and an aligned binary decomposition bounds every initial partial sum. There is no probabilistic oracle, Khintchine hypothesis, numerical testing dependency, new axiom, or unchecked evaluation in this argument.

This is a general theorem, not a new paper endpoint assumption. The next milestone consumes the proved constant in the public Section7 and near-L1 exports and completes the paper-wide source/assumption audit. All 54 numbered paper targets retain their existing source statuses; no extra paper result is counted merely because supporting lemmas were added. The deep inputs previously excluded from scope remain explicit. The user is applying manuscript edits, and no revised upload is presumed.

The full quantitative Goldbach theorem is proved conditionally at every large real cutoff X; the supplied presieving replacement still needs to be copied into the user manuscript. Section9 also includes a proved full primitive two-square criterion and convergence of W(alpha) for every alpha>1. The old parameterized theorems remain for compatibility; the current matched exports remove those discharged parameters. The user is applying manuscript edits and their application has not been verified against a new upload.

`Checkpoint_1264_PaperClosedSignedMaximal.md`

Checkpoint 1264: Reviewed corrected paper complete in the agreed conditional scope

The paper-wide review is complete for the selected corrected target. Every declared theorem-like environment is checked against the source ledger: 54 numbered theorem/proposition/lemma/corollary targets and four definitions. The reviewed statuses are 22 proved under ordinary source hypotheses, 31 complete implications from explicit independent inputs, one quoted external Granville–Kurlberg theorem, and zero open internal numbered endpoints. Exact statements, quantifiers, source hashes and evidence are preserved; no supporting-theorem percentage is claimed.

The four current public Section7/near-L1 exports now consume the proved finite signed maximal theorem at constant6. theorem_7_2_closed_signed_maximal, corollary_7_6_closed_signed_maximal, corollary_7_46_closed_signed_maximal and theorem_1_5_ii_closed_signed_maximal have the full existing source conclusions without a supplied RawFiniteSignedMaximalInput or its parameter R. All other documented independent inputs retain their precise scopes. The older parameterized results remain for compatibility.

A reproducible paper completion audit checks all declared theorem-like environment types, label and hash coverage, every current evidence declaration type in Lean, and the actual discharge of the signed maximal and primitive-criterion parameters. The complete type output is saved. The full build, source scan and complete transitive axiom audit are run; no own-paper endpoint is added as an independent input.

The current plan, Section11 plans, earlier-sections summary and signed maximal boundary are reconciled. Prior planning versions are preserved in the archive directory. The exact independent analytic/ergodic/sieve boundaries are summarized in docs/INDEPENDENT_INPUTS_CURRENT.md. Proving those inputs is a separate optional development within the previously agreed scope.

The user is applying the previously supplied manuscript corrections. No new upload or application is presumed, the original sources remain unchanged, and the reviewed corrected presieving target is still explicit. No additional replacement passage is required by this continuation. The audit does not claim proofs of independent deep inputs or every stronger unnumbered assertion in alternative proof routes. See docs/PAPER_COMPLETION.md for the final result matrix and verification scope.

The complete upper-sieve proposition and strict numerical comparison are proved conditionally with exact constants and uniform quantifiers. The joint Section11 estimates are proved at one cutoff. The full quantitative Goldbach theorem is proved conditionally at every large real cutoff X; the supplied presieving replacement still needs to be copied into

the user manuscript. Section9 also includes a proved full primitive two-square criterion and convergence of W(alpha) for every alpha>1. The old parameterized theorems remain for compatibility; the current matched exports remove those discharged parameters. The user is applying manuscript edits and their application has not been verified against a new upload. The finite signed maximal theorem is proved internally at constant6 and consumed by current Section7, Corollaries7.6/7.46 and Theorem1.5(ii) exports. No supplied signed maximal hypothesis remains in those exports. Read docs/PAPER_COMPLETION.md and docs/INDEPENDENT_INPUTS_CURRENT.md for the complete current scope.

`Checkpoint_1265_ManuscriptReviewAndFullRebuild.md`

Checkpoint 1265: Current manuscript review and fresh full rebuild

The current complete manuscript has been reviewed directly against the checked source and Section11 replacement. It retains all54 numbered results and4 definitions with the same stable labels. Of the58 statements,57 are unchanged modulo whitespace. The only rewritten statement is the presieving lemma. Its corrected hypotheses and conclusion are retained, and the rewrite is covered by three new proved Lean equivalences: the old strict D0<D condition follows from the current level chain, and the inline preliminary/outer prime conditions define the same interval products.

The changed proof passages are reviewed separately: both approximation branches and periodized lifts, ordinary unweighted SW/BV major approximation with the strict endpoint and q+1 finite errors, refined interval dimensions, preliminary coefficient bounds, uniform lower/upper sieve levels, exact weighted integration constants and discarded-range absorption. They preserve the checked source conclusions and use the same documented independent inputs. No new independent mathematical hypothesis is introduced.

One cleanup is needed: two consecutive identical displays carry the label e:integratedW10. Keep the first and remove the preceding Therefore plus the second copy. No mathematical replacement is required. The original upload is preserved byte-for-byte; a complete cleaned TeX copy, exact deletion fragment and minimal patch are supplied. All numbered statement bodies are identical between the upload and cleaned copy; the cleanup removes the duplicate label without changing the formalization target.

The entire local project is freshly rebuilt from source, with project build traces removed and remote project artifact reuse disabled. All source scans, complete transitive theorem axiom audits and current paper evidence declaration-type checks are rerun. The project retains pinned Lean4.34.1 and Mathlib revisiond13f23b723b8a846827a245b89c10fc7d3f11612. The final verification below records the actual counts.

All54 numbered targets retain their agreed scopes:22 proved under ordinary source hypotheses,31 complete implications from explicit independent general inputs, one quoted external theorem, and no open internal numbered endpoint. All4 definitions are formalized. The independent deep analytic, sampling, ergodic, Weil and sieve theorem inputs and their formulation bridges remain unproved; the axiom audit checks the deductions and does not establish those input truths. No blanket claim is made for stronger unnumbered alternative-route assertions. The current upload's mathematical edits are verified; the earlier pending manuscript synchronization status is resolved.

Checked declarations

Module	Named supporting theorems
GoldbachPresieveSourceEquivalence.lean	3

- `goldbach_current_presieve_strict_level`
- `goldbach_current_presieve_preliminary_filter`
- `goldbach_current_presieve_outer_filter`

Bibliography check: the uploaded TeX cites Ghosh1981, which is absent from the bibliography saved with this project. The user's local bibliography was not supplied, so no absence is presumed there. A reviewed bibliography adds only that entry: A.Ghosh, The Distribution of alpha p squared Modulo1, Proceedings of the London Mathematical Society s3-42(2),252–269(1981), DOI10.1112/plms/s3-42.2.252. These details are checked against the primary publisher record at https://doi.org/10.1112/plms/s3-42.2.252. If the user's own .bib already contains that key, no bibliography edit is needed. The reviewed manuscript bundle supplies a matching BibPrimeSquares.bib; all earlier entries are preserved. This is a bibliography repair, not a new mathematical hypothesis or proof.

<!-- checkpoint-verification -->

Verification

All 1382 project modules and the root were freshly rebuilt: 5179 jobs pass without warnings/errors. All 4517 named theorems pass the complete transitive axiom audit, allowing only propext, Classical.choice and Quot.sound. The source scan checks 1384 Lean files. Exact unique import/audit coverage and unchanged frozen source hashes are checked before packaging. There are no placeholders or added mathematical axioms.

The complete28 October2026 user upload is reviewed directly: all54 numbered results and4 definitions are matched in the agreed conditional scope. The presieving rewrite retains the corrected hypotheses and is covered by three proved Lean equivalences; no mathematical replacement remains pending. One repeated e:integratedW10 display needs the supplied cosmetic cleanup. The entire project and root are freshly rebuilt from source with full source, theorem-axiom and declaration-type audits. Independent general inputs and their formulation bridges remain explicit and unproved. The original upload and earlier frozen sources are unchanged; a one-display cleanup copy is separately supplied.

Batch summaries

Batch_42_91_Report.md

Prime Squares: combined report for checkpoints 42–91

Fifty separately saved proof checkpoints continue checkpoint 41. This batch adds 95 named supporting theorems in 50 modules; the project now has 940 named supporting theorems in 158 modules. These counts describe supporting formal work, not newly completed numbered manuscript results.

What this batch establishes

1. The genuine finite real model's major-arc error has a logarithmic rate with a single natural-number threshold independent of Q, the chosen finite rational-center set and exceptional data, conditional on the explicitly displayed actual progression-prefix estimate.
2. Actual annular integrals and localized Gauss models are continuous in frequency. Their compact symbols have a genuine continuous unit-circle periodization, globally identified with the integer-translate sum. Boundary aliases are included.
3. Finite rational-center sums define genuine global continuous model, error, low and high candidate symbols. Their inverse Fourier kernels and compatible l1-to-linfinity / l2 operators are constructed. The actual annular von-Mangoldt square kernel and every finite complex input have exact low + high + error decompositions.
4. Infinite convolution by a bounded kernel is proved absolutely convergent on every l1 input. The resulting bounded linear operator agrees with the Fourier l2 operator on finite inputs. Kernel-sensitive bounds, denominator-weighted Gauss estimates and finite-family l2 envelopes are proved.
5. The narrow-to-broad cutoff containment is proved. The compact low and high real symbols equal the original paper formulas under the displayed scalar conditions, including Q*q0/B0<=R for the exceptional width. This condition is not silently inferred from unproved conductor data.
6. An explicit assembly theorem connects these actual operators to OperatorHighLowBound at the correct spatial scale N^2. Its sharp low-kernel and combined high/error-symbol bounds remain displayed inputs, not proved source estimates.

What remains open

Theorem 1.1 is NOT proved. Neither are full Lemma 6.5, global approximation 6.9, sharp low 6.14, multifrequency 6.16, high/maximal 6.21 or Proposition 4.19. The full-range minor-arc deduction from the verified Ren estimate remains unresolved. The exact manuscript center set, the full exceptional parameter range and the sharp analytic kernel/operator estimates must still be connected to the constructions here.

The raw progression-prefix estimate remains an explicit unproved deep-input hypothesis. No existence theorem for uniform exceptional data has been registered. Lemma 3.21 still uses its two earlier explicit PNT limits; the separate PNT development is not imported or claimed integrated.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, abstract Theorem 4.1 and abstract Corollary 4.15, with their previously recorded source hypotheses.

Correctness and verification

Lean 4.34.1 and Mathlib d13f23b723b8a846827a245b89c10fc7d3f11612 remain pinned. The recovered checkpoint-41 ZIP was tested and every archived file hash verified. The official Lean archive SHA256 and all nine exact dependency revisions were checked before continuing.

Every checkpoint has a successful dependency-aware build, complete source scan and fresh complete transitive-axiom audit for every named theorem. Reused old project proof sources and compiled artifacts are authenticated by SHA256 receipts. New modules and changed root imports are compiled with remote project artifact reuse disabled. Checkpoints 42, 74 and 91 use fresh full project rebuilds. The final build and audits must all pass before this report is saved.

One attempted checkpoint-74 root artifact failed the independent audit because it did not expose the new import, although direct import of the new module succeeded. The failed attempt was rejected and preserved in verification/rejected-attempt74. Build artifacts were isolated from workspace synchronization and the entire project freshly rebuilt and audited successfully before checkpoint 74 was saved. No rejected attempt counts as a completed checkpoint.

Only propext, Classical.choice and Quot.sound are allowed in the complete transitive axiom audit. There are no sorry/admit placeholders, added mathematical axioms, unsafe declarations or native_decide proofs. No new numerical experiment is substituted for an analytic proof. Earlier exact numerical reports and script hashes are preserved.

Every checkpoint ZIP contains the cumulative proof sources, expositions, source correspondence, current verification logs, assumption/scope notes, inventory and restart instructions. Its SHA256 manifest and every ZIP entry are verified. Reproducible dependency/build caches are excluded. The original manuscript and accepted revision fragments retain their frozen hashes.

Manuscript replacements

No additional mathematical error or justified replacement was established in this batch. The manuscript and earlier accepted corrections were left unchanged. An open proof obligation is not reported as a counterexample or converted into an unproved axiom. The corrected Lean sources and verification infrastructure are included in every subsequent cumulative archive.

Checkpoint ledger

Each archive below is cumulative. All 50 are saved separately; the final archive contains the full latest project. The checkpoint-specific exposition records the exact new declarations and limitations.

Checkpoint	Proof unit	New named supporting theorems	Archive

Resume

Extract the latest archive and read STATUS.md, docs/CONTINUE_HERE.md and docs/ASSUMPTIONS.md. Use the pinned toolchain and source revisions. A standard installation runs `lake build`, `python3 scripts/check_source.py` and `python3 scripts/check_axioms.py`. Local build artifacts are reproducible and are not included in the archive. The compatibility wrapper and narrow process-executable shim are documented in verification/ENVIRONMENT.md; no compiler or kernel modification is involved.

Next checkpoint: 92. Prioritize the full-range minor-arc/global approximation gap and the sharp source-specific low/high estimates; the circle/kernel/operator constructions in this batch should be reused.

`Checkpoints_92_96_Report.md`

Prime Squares: checkpoints 92–96

Five separately verified checkpoints add **28 named supporting theorems in five modules**. The final project has **163 modules and 968 named supporting theorems**. These are counts of supporting declarations, not counts of completed manuscript results.

The main advance is a proof of the actual periodized circle-model approximation on the major-arc and intermediate-denominator branches, conditional on the explicit progression-prefix estimate. The finite rational indexing and integer shifts are now handled exactly. The full minor-arc range and Theorem 1.1 remain open.

Saved checkpoints

Checkpoint	Mathematical unit	Added theorems	Project total	Archive and exposition
95	Conditional major-arc error for the actual circle model	4	965	ZIP / Proof notes
96	Conditional intermediate-denominator circle approximation	3	968	ZIP / Proof notes

Each ZIP contains the complete project at that checkpoint, its proof notes, verification logs, frozen source materials, accepted revisions, dependency pins and continuation notes. Checkpoint 96 includes all five new modules and their expositions. Dependency caches are reproducible and excluded. Earlier checkpoints were saved before the subsequent production-tree changes.

What the proofs establish

`CanonicalRationalCenters.lean` constructs a finite set with membership exactly equivalent to $0 \le r < 1$ and $\mathrm{den}(r) \le R$. It accounts for all reduced canonical rationals, the empty zero cutoff, monotonicity and the denominator-one center zero. It does not assert the full character/coefficient summation correspondence with the manuscript.

`WrappedRationalArcGeometry.lean` proves separation of different rational-center/integer-lift pairs, uniqueness of sufficiently narrow arcs, and exclusion of all other lifted arcs. Integer shifts of a real representative give exactly the same point of the circle. Distinct lifts of the same rational are included in the proofs.

`PeriodizedModelTails.lean` writes the genuine periodization exactly as five shifts on the representative interval $[-1, 2]$. It proves an outside-arc norm bound of size $O((1+\log R)R^{-5/12})$ for the actual circle model. The fixed constants and budgets are defined in Lean. A common approximation budget is eventually at most $R^{-1/6}$ and has a threshold uniform over $Q \ge 1$ at the source scale.

`PeriodizedMajorArcError.lean` bounds the actual circle error on a major arc. The argument retains the four additional shifts of the real model and bounds them using the lifted separation theorem. It includes the shifted copies of the selected center itself. No periodicity is assumed for the continuous real-variable oscillatory integral.

`IntermediateCircleApproximation.lean` treats an approximating denominator $R < q \le R^{11/10}$ on the branch outside every small-denominator lifted major arc. It derives a bound for the actual von Mangoldt multiplier from the progression estimate and unconditional Gauss bounds, then subtracts the actual circle model. The geometric outside-arc condition and existence of the chosen approximation are explicit hypotheses of this branch.

Both conditional approximation branches give

$$\|E_{N,Q}(\xi)\| \le 2^A Q^{-1/2}(1+\log N)^{-A}$$

for all sufficiently large N, with one threshold independent of the permitted Q and exceptional data. Here $A \ge 0$, $Q \ge 1$, $R = \max(\exp((\log N)^{1/10}), Q^8)$, and $\log Q \le \min(c/7, 1)\sqrt{\log N}/8$. The relevant lifted arc, coefficient bounds, $0 < \beta \le 1$ and raw progression-prefix hypotheses remain explicit in the theorem statements.

Analytic assumptions and open work

The deep input is still a hypothesis bounding the actual `progressionMangoldtPrefix` minus `progressionPowerModel` by $NC\exp(-c\sqrt{\log N})$, for every unit residue and every real endpoint in $[N/2, N]$. The same character, coefficient and beta data are required throughout that interval. This input has not been proved in the project and is not introduced as an axiom. The source-scale inequalities are proved by existing threshold lemmas. The Gauss estimates used in these five units are already proved unconditionally in the project.

The missing range $q > R^{11/10}$ has not been filled by assuming the manuscript's minor-arc conclusion. Full Lemma 6.5, global Lemma 6.9, sharp low 6.14, multifrequency 6.16, high/maximal 6.21, Proposition 4.19 and **Theorem 1.1 remain open**. The full exceptional-parameter/source correspondence is also incomplete. Lemma 3.21 retains its two earlier explicit PNT limits; the separate PNT development has not been integrated by this batch.

The ten completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, abstract Theorem 4.1 and abstract Corollary 4.15 under their recorded source hypotheses. This batch does not establish a full-paper correctness or publication certification claim.

No new manuscript error has been established. No additional LaTeX replacement is prescribed. The frozen manuscript and the two accepted revisions remain unchanged.

Verification

The final checkpoint passes a fresh **3682-job full build of all 163 modules and the root**, with no warnings or errors. All **968 named theorems** pass a fresh complete transitive axiom audit allowing only `propext`, `Classical.choice` and `Quot.sound`. All **165 Lean files** pass the source scan: no placeholders, additional mathematical axioms, unchecked evaluation or unsafe code. Import and axiom-audit coverage are exact and unique. Complete output and source/artifact hashes are retained.

Checkpoint 92 also began with a fresh full rebuild after restoring the pinned environment. Checkpoints 93–95 used authenticated dependency-aware builds: earlier proof sources and compiled artifacts were SHA256 checked before reuse, and each new module and the root were compiled. Every checkpoint ran the complete source and transitive-axiom audits. The final full rebuild removes dependence on incremental history for the final verification result.

Lean 4.34.1 (commit `5045d0056413266e57c625dcd7c365b10e377c52`) and Mathlib `d13f23b723b8a846827a245b89c10fc7d3f11612` remain pinned. All nine dependency revisions were restored exactly. The official Lean archive hash was verified during recovery. The documented process-path compatibility shim does not modify Lean's compiler or kernel. GitHub CI is configured but has not run on GitHub.

Every checkpoint ZIP is CRC tested, and every archived project file is checked against its SHA256 manifest. The frozen manuscript hashes and both accepted revision hashes are checked. These new analytic results are Lean proofs; no new numerical experiment is used as a substitute. Earlier exact finite experiments and their script hashes are preserved.

Resume

Start from `PrimeSquares_Checkpoint_96.zip`, verify its manifest, and read `STATUS.md`, `docs/CONTINUE_HERE.md` and the five new expositions. The next checkpoint is **97**.

The next mathematical priority is the large-denominator/full-range minor-arc deduction. Check the exact uniform range and constants in a primary-source estimate before using it; do not vary a fixed epsilon with N or assume an uncontrolled own-paper conclusion. Then complete global approximation, connect the exceptional data and prove the sharp operator estimates needed for Proposition 4.19 and Theorem 1.1. The conditional major/intermediate circle branches and earlier exact operator assembly are already complete and should not be repeated.

`Checkpoints_97_146_Report.md`

Prime Squares: checkpoints 97–146

This batch contains **50 separately verified checkpoints**, adding **136 named supporting theorems in 50 modules**. The final project has **213 modules and 1104 named supporting theorems**. These are counts of supporting declarations, not counts of completed manuscript theorems.

The main mathematical advance is a conditional global circle-model approximation and a conditional quantitative countable dyadic maximal-error bound. A new complementary minor-arc argument resolves the range left uncovered by direct substitution into Ren's estimate. Theorem 1.1 and the separate sharp low/high inputs remain open.

Mathematical results

Write $x = N/2$ and $R = \max(\exp((\log N)^{1/10}), Q^8)$. The argument uses the actual annular von Mangoldt square multiplier, its actual continuous periodized circle model, and the corresponding genuine bounded operators on $\ell^2(\mathbb{Z})$.

1. **An unconditional divisor budget.** For every fixed positive exponent, the divisor count is bounded by a constant times that power of the denominator. The proof starts from the prime-power exponent factors, uses unique factorization, and retains all constants. In particular, $\tau(q)^{3/2} \le Dq^{1/12}$ with one fixed positive D.
2. **A compatible new rational selection.** Dirichlet approximation constructs a reduced rational a/q with $q \le x^{3/2}$ and $|\theta| \le 1/(qx^{3/2})$, where $\theta = \xi - a/q$. The strict error $|\theta| < 1/q^2$ is proved as well.

Normalization by the rational fractional part preserves the reduced denominator and identifies the exact integer lift of a canonical center.

3. **The complementary full-complement minor argument.** If $q \le \sqrt{x}$, the effective denominator $T = q(1+|\theta|x^2)$ is at most $2\sqrt{x}$. Exclusion from all small-denominator lifted source arcs forces $T \ge R/4$. Retaining the divisor loss, the three normalized Ren terms are bounded by

$$\sqrt{2}\,x^{-5/24}, \qquad x^{-19/120}, \qquad 4^{5/12}R^{-5/12}.$$

The source parameter budget implies $R^4 \le x$, so these give a bound of the form $K_{\mathrm{Ren}}(\log x)^d R^{-5/12}$. If $q > \sqrt{x}$, it lies in the balanced Ghosh range $[\sqrt{x}, x^{3/2}]$. The fixed choice $\varepsilon = 1/16$ gives a normalized saving $x^{-1/16} \le R^{-1/4}$. No fixed epsilon is changed with N. Combining the branches proves the alternative full-complement bound

$$|\widehat{\widetilde{A}}_{N,\Lambda}(\xi)| \le K_{\mathrm{Ren}}(\log(N/2))^d R^{-5/12} + K_{\mathrm{Gh}} R^{-1/4}.$$

The constants are defined in Lean, and the raw Ren and Ghosh inequalities remain explicit hypotheses. This is a weaker alternative to the stronger printed minor formula in Lemma 6.5; that printed formula is not claimed to be proved or disproved.

4. **Global circle approximation.** Logarithmic losses are absorbed uniformly in Q. A complete case split over the exact source rational set and every integer lift combines the major branch with the alternative minor branch. Every circle point is covered through a proved fundamental representative interval. Under the explicit analytic inputs, for every $A \ge 0$ and all sufficiently large N,

$$\|E_{Q,N}\|_{\ell^2 \to \ell^2} \le 2^{A+1} Q^{-1/2} (1+\log N)^{-A}.$$

The same bound holds for the actual circle error at every frequency. One threshold is chosen before all permitted Q and character/coefficient/beta data.

5. **A true countable maximal error.** The actual dyadic error operators have a summable norm tail. An absolutely convergent positive vector sum is constructed in real ℓ^2, its coordinate series is identified at every integer, and it is proved to dominate the genuine countable supremum. That supremum is itself realized in ℓ^2. At a starting dyadic scale $N_0 = 2^J$, the result is

$$\left\| \sup_{j \ge 0} |E_{Q,2^{J+j}} f| \right\|_2 \le C_A Q^{-1/2} (1+\log N_0)^{-A} \|f\|_2.$$

The Q condition is imposed at the starting scale and proved at every larger scale. The character, coefficient and beta data may vary between scales. The supremum covers the entire infinite tail, not only finite truncations.

6. **Continuation and pairing properties.** The actual maximal map is sublinear and Lipschitz. Norm-summable operator outputs vanish in ℓ^2 and at every integer coordinate, and their maximal tails vanish in ℓ^2. Exact operator identities identify the error with the actual average minus its circle model. The global error bound also yields finite-indicator pairings bounded by the error norm times $\sqrt{|F||G|}$, with the precise density normalization recorded.

Explicit inputs and scope

The hypothesis structure `CircleAnalyticInputs` contains beta/coefficient conditions and the following raw deep estimates. It contains no desired approximation or maximal-operator conclusion.

Input	What remains assumed
Progression prefix	The actual `progressionMangoldtPrefix` minus `progressionPowerModel` is bounded by $NP\exp(-c\sqrt{\log N})$ for every source denominator, unit residue and real endpoint in $[N/2, N]$. One set of scale data must work throughout that interval.
Ren	The displayed three-term estimate for the actual annular positive-phase prime-power sum, with its full $\tau(q)^{3/2}(\log x)^d$ prefactor, at compatible approximants.
Ghosh	The displayed fourth-root estimate for the actual quadratic sum at compatible approximants, with fixed $\varepsilon = 1/16$, the balanced denominator range and strict reciprocal-square error.

These published deep estimates are consumed as theorem hypotheses, as authorized. They are not formalized here, added as axioms, or replaced by numerical checks. The scalar constants are fixed before the varying scale, frequency, denominator and input function.

The common permitted range is $Q \ge 1$ and

$$\log Q \le \frac{\min(c/7,1)}{8}\sqrt{\log N}.$$

For a dyadic tail it suffices to impose this condition at its starting scale. Thresholds may depend on the fixed analytic constants and A, but not on Q or the later scale data.

The primary estimates were checked against Xiumin Ren's author preprint, On exponential sum over primes and application in Waring-Goldbach problem, Theorem 1.1 and equation (1.4). Ghosh's original article is The Distribution of alpha p squared Modulo 1, Theorem 2; its first-page transcription was also inspected at this copy. The original Ghosh publisher PDF was inaccessible; Ren's primary text supplies the directly displayed annular estimate. The exact raw inequalities and compatibility hypotheses used in Lean are visible in `RenBalancedInput`, `GhoshBalancedInput` and the consuming modules.

The stronger printed minor estimate of Lemma 6.5 remains open. The complete exceptional-parameter/source correspondence and exact double-sum bridge have not been silently certified by `CircleAnalyticInputs`. The full source version of Lemma 6.9 therefore still needs those bridges, even though the conditional global pointwise/operator approximation for the constructed circle model is proved. Sharp low 6.14, multifrequency 6.16, high/maximal 6.21, Proposition 4.19 and **Theorem 1.1 remain open**. The maximal error estimate above concerns the error component and does not bound the separate high operator.

The ten earlier completed numbered results remain 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, abstract Theorem 4.1 and abstract Corollary 4.15 under their recorded hypotheses. Lemma 3.21 retains its two earlier explicit PNT limits; the separate PNT project has not been integrated. There is no full-paper correctness or publication-certification claim.

No new manuscript statement error has been established, so no mandatory LaTeX replacement is prescribed. The alternative deduction is fully recorded in the new Lean modules and their expositions. The frozen manuscript and the two accepted revisions remain unchanged.

Verification

The final checkpoint passes a fresh **3738-job full build of all 213 modules and the root**, with no warnings or errors. All **1104 named theorems** pass a fresh complete transitive axiom audit permitting only `propext`, `Classical.choice` and `Quot.sound`. All **215 project Lean files** pass the source scan: no placeholders, extra mathematical axioms, unchecked evaluation or unsafe code. Import and audit coverage are exact and unique.

The baseline checkpoint 96 source/artifact hashes were verified before continuing. Every new checkpoint compiled its new module and the root and ran complete source and transitive-axiom audits. Unchanged earlier proof sources and compiled artifacts were SHA256 checked before incremental reuse. Checkpoints 121 and 146 performed fresh full project rebuilds. Verification logs and build receipts identify the exact compiled modules and complete dependency history.

Lean 4.34.1 (commit `5045d0056413266e57c625dcd7c365b10e377c52`) and Mathlib `d13f23b723b8a846827a245b89c10fc7d3f11612` remain pinned. No compiler/kernel modification or version upgrade was made. GitHub CI is configured but has not run on GitHub.

Each checkpoint ZIP is CRC tested, and every archived project file is checked against its SHA256 manifest. Frozen manuscript and accepted revision hashes are checked. These new analytic statements are Lean proofs; no new numerical experiment is used as a substitute. Earlier exact finite experiments and matching script hashes are preserved.

A final download check found 19 truncated archive transfers. Their complete entries were recovered with CRC checks and missing historical logs restored from the retained snapshots. The original file counts and every original Lean source hash were verified against the corresponding build receipts. The archives were replaced under their existing identities and checked again, including their SHA256 manifests. No mathematical proof was changed by this repair. The packaging script now publishes a complete ZIP by atomic rename so that a partially written archive cannot be selected during generation.

All fifty checkpoints

Each ZIP is a complete project snapshot with its proof notes, logs, source materials and restart instructions. The final ZIP includes all fifty new modules and expositions. Reproducible dependency caches are excluded. Each checkpoint was saved before the following production-tree mutation.

Checkpoint	Mathematical unit	Added theorems	Project total	Build	Archive and exposition
97	A fixed-epsilon Ghosh bound in the balanced denominator range	5	973	incremental	ZIP / Proof notes

Continue from checkpoint 147

Recover `PrimeSquares_Checkpoint_146.zip`, verify its archive manifest, and read `STATUS.md`, `docs/CONTINUE_HERE.md`, this report and the relevant individual expositions. The next checkpoint is **147**.

The next mathematical priority is the genuine low-kernel estimate 6.14 and the sharp ordinary/exceptional high and multifrequency inputs 6.16/6.21. Complete the exceptional-data and exact source summation bridges before identifying the constructed model with every printed manuscript object. Then finish Proposition 4.19 and connect Theorem 1.1. The conditional global error, its alternative minor argument and its countable maximal-tail analysis are already complete and should not be repeated. Keep the stronger printed minor formula explicitly open unless a separate proof is supplied.

`Checkpoints_147_246_Report.md`

Prime Squares: checkpoints 147–246

This batch contains **100 separately verified checkpoints**, adding **217 named supporting theorems in 100 modules**. The final project has **313 modules and 1321 named supporting theorems**. These are supporting-declaration counts, not counts of completed manuscript results.

The main advance is a genuine denominator-indexed circle low multiplier, with its inverse kernel identified and its local and all-input operator estimates proved in the stated natural-cutoff range. The batch also develops countable square-function and maximal estimates, including an applicable criterion for actual circle multipliers. **Theorem 1.1 remains open.**

Mathematical results

1. **An actual smooth inverse cutoff.** The source smooth bump is proved to be Schwartz. Its inverse Fourier transform has rapid decay of every natural order. A proved real change of variables identifies the inverse transform of the frequency dilation with the physical dilation $a^{-1}\check{\eta}(x/a)$. Phase signs, complex scalars and normalizations are retained.
2. **The smoothed annular kernel.** For $N \geq 2$, $\beta \leq 1$ and $0 < a \leq N^2$, the actual kernel

$$K_{N,\beta,a}(x) = \frac{1}{N}\int_{N/2}^{N} t^{\beta-1}a^{-1}\check{\eta}((x-t^2)/a)\,dt$$

   is integrable in its defining variable and satisfies the proved rapid-decay envelope

$$|K_{N,\beta,a}(x)| \leq \frac{2^k C_k}{2a}\left(1+\frac{|x|}{N^2}\right)^{-k}.$$

   The constants C_k come from the actual inverse cutoff. The argument includes the scale comparison between x and $x-t^2$. It does not assume the desired spatial decay.
3. **Logarithmic arithmetic summation.** The ordinary truncated Cohen bound is assembled from the actual quadratic sums. For the exceptional arithmetic factor

$$\rho(n) = \prod_{p\mid n}\frac{p+1}{p-1},$$

   prime-subset expansion, divisibility and reciprocal-multiple sums prove

$$\sum_{n=1}^{D}\frac{\rho(n)}{n} \leq e^2 H_D \leq e^2\left(1+\frac{1}{\log 2}\right)\log(2D), \qquad D \geq 1.$$

   This estimate holds for all positive denominators; no squarefree restriction is needed for this upper bound. The correction Euler product is bounded by e^2. No PNT or Mertens hypothesis is used. The previously proved conductor-sensitive estimate for the actual induced twisted correlations supplies the exceptional coefficients.
4. **The ordinary minus exceptional physical low kernel.** The ordinary widths are qN^2/Q; the exceptional widths are $B_0 dN^2/Q$, with $B_0 = \texttt{conductorMajorant}(q_0)$. The arithmetic factor B_0 cancels against the exceptional smoothing width. For natural $N, Q \geq 2$, a positive conductor, a quadratic base character, $\beta \leq 1$, $S \subseteq \{1,\dots,Q\}$, and $B_0 d \leq Q$ for every $d \in S$, the actual complex kernel satisfies

$$|L_{N,Q}(x)| \leq C_{\text{low}}\frac{Q\log(2Q)}{N^2}\left(1+\frac{|x|}{N^2}\right)^{-10}.$$

The finite Gauss/unit sums and induced twisted coefficients are retained, with the exceptional term subtracted. The empty exceptional range is handled separately. The absolute constant is defined in Lean from the cutoff and arithmetic constants.

5. **Local convolution and genuine low operators.** A complete dyadic partition of integer distances includes every boundary and the inner shell. It gives, for every finite complex input, a convolution bound by $4C_{\mathrm{low}}Q\log(2Q)$ times the proved normalized dyadic local mass at scale N^2. The kernel also yields an all-input $\ell^1 \to \ell^\infty$ bound

$$\|L_{N,Q}\|_{\ell^1\to\ell^\infty} \le C_{\mathrm{low}}\frac{Q\log(2Q)}{N^2}.$$

Finite-indicator pairings and far-field decay follow. Uniformly bounded families admit a genuine countable $\ell^1 \to \ell^\infty$ maximum, including varying conductor, character and beta data between scales.

6. **The inverse-kernel identity for genuine circle symbols.** The compact frequency cutoff is passed to the circle, with the closed fundamental endpoints and every integer lift checked. Joint continuity and integrability justify the annular Fubini interchange. The resulting circle Fourier coefficient equals the actual smoothed physical kernel. Frequency shifts give the correct positive physical modulation. Summing over positive denominators and unit residues defines `denominatorCircleLow`, and its inverse kernel is proved equal to the physical low kernel above. The extra width budget $2Q \le N^2$ makes every contributing cutoff narrow enough for this circle construction. Thus the displayed local and ℓ^1 estimates hold for this actual Fourier multiplier, not just an abstract kernel majorant.
An all-input convolution series for every continuous circle symbol is also proved in ℓ^2 through density/continuous linear maps, and its ℓ^1 realization agrees with the actual ℓ^2 multiplier on the inclusion of ℓ^1. The `LowSymbolData` structure records only scale, character and width conditions; it contains no desired norm estimate. The exact all-real-lift formula for these circle symbols is recorded.

7. **Countable square functions and maxima.** For any sequence $F_j \in \ell^2(\mathbb{Z})$ with $\sum_j \|F_j\|_2^2 < \infty$, the double series of coordinate squares is summable. Its two orders of summation agree. The genuine pointwise square function is realized in real ℓ^2 with

$$\left\| \left(\sum_j |F_j|^2 \right)^{1/2} \right\|_2^2 = \sum_j \|F_j\|_2^2.$$

It dominates the actual countable pointwise supremum, which is itself realized in ℓ^2. Uniform finite energy bounds imply the countable maximal bound. This requires summability of squared output norms, a weaker condition than the earlier sum-of-output-norms construction. Operator versions, squared-operator-norm criteria, quantitative tail bounds, tail convergence to zero, sublinearity and Lipschitz control are proved.

8. **Actual annular collar decay and multiplier energy.** For $M \ge 2$, $\beta \in [0,1]$, $q, Q > 0$ and $|\theta| \ge Q/(2qM^2)$, the actual annular model at 2^jM satisfies

$$|\mathcal{A}_{2^jM,\beta}(\theta)| \le \frac{4q}{\pi Q}4^{-j}, \qquad \sum_{j\ge 0}|\mathcal{A}_{2^jM,\beta}(\theta)|^2 \le \frac{16}{15}\left(\frac{4q}{\pi Q}\right)^2.$$

First collar onset and exact finite energy decomposition under disjoint frequency support are proved as well. For continuous circle symbols m_j, the explicit finite-frequency energy condition

$$\sum_{j\in J}|m_j(\xi)|^2 \le B^2 \quad \text{for every finite } J \text{ and every circle point } \xi$$

implies the genuine countable operator bound

$$\left\| \sup_{j\ge 0}|T_{m_j}f| \right\|_2 \le B\|f\|_2.$$

The implication is proved by integration, the Fourier isometry and the countable square-function construction. Pointwise attenuation of the symbols preserves this conclusion. **The frequency energy condition has not yet been verified for the paper's complete high/multifrequency family.** This criterion is supporting infrastructure, not a completed proof of those source estimates.

Exact scope and remaining obligations

The new low estimates are unconditional within their displayed scale, character and finite-denominator hypotheses. The new square-function results are proved implications from their stated energy assumptions. No new deep analytic result, own-paper conclusion or mathematical axiom is introduced in this batch.

The low circle model uses natural $N, Q \geq 2$ with $2Q \leq N^2$ and the stated exceptional width budget. The general real-cutoff rounding and the exact identification with the earlier rational-indexed global approximation model remain open. The local result covers finite complex inputs; the global $\ell^1 \to \ell^\infty$ result covers all ℓ^1 inputs. These distinctions prevent a claim that every version and domain of the source low lemma 6.14 has been completed.

The earlier conditional global circle approximation and its countable dyadic maximal-error result remain valid under their explicit raw progression-prefix, Ren and Ghosh hypotheses. Those deep estimates have not been formalized here. The stronger printed minor formula in Lemma 6.5 and the complete exceptional-data/source summation correspondence remain open. The sharp high and multifrequency estimates 6.16/6.21, Proposition 4.19 and **Theorem 1.1 remain open**. The new low proof and generic square-energy criterion do not silently discharge these obligations.

The earlier ten completed numbered results remain recorded with their exact scopes: 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, abstract Theorem 4.1 and abstract Corollary 4.15. Lemma 3.21 retains its two earlier explicit PNT limits; no separate PNT formalization has been integrated. There is no claim of full-paper correctness or publication certification.

No new manuscript statement error has been established in this batch, so no mandatory LaTeX replacement is prescribed. The frozen manuscript, bibliography and two accepted source revisions remain unchanged. New deductions are explained in the Lean modules and individual proof notes.

Verification

The final checkpoint passes a fresh **3920-job full build of all 313 modules and the root**, with no warnings or errors. All **1321 named supporting theorems** pass a fresh complete transitive axiom audit allowing only `propext`, `Classical.choice` and `Quot.sound`. All **315 project Lean files** pass the source scan: no proof placeholders, extra mathematical axioms, unchecked evaluation or unsafe code. Import and audit coverage are exact and unique.

The baseline checkpoint 146 source/artifact hashes were checked before continuing. Every new checkpoint compiled its new module and the root and ran complete source and transitive-axiom audits. Before incremental reuse, SHA256 checks authenticated earlier proof sources and compiled artifacts. Checkpoints **171, 196, 221 and 246** performed fresh full project builds. Logs and build receipts record exact source/artifact hashes and build history.

Lean 4.34.1 (commit `5045d0056413266e57c625dcd7c365b10e377c52`) and Mathlib `d13f23b723b8a846827a245b89c10fc7d3f11612` remain pinned. Additional Fourier/Schwartz dependencies were built from that same Mathlib source. No compiler/kernel modification, toolchain upgrade or dependency version change was made. GitHub CI is configured but has not run on GitHub.

Every new ZIP is published atomically after CRC testing and checking every archived file against its SHA256 manifest. Frozen manuscript/revision hashes and source build receipts are checked. Every checkpoint is saved before the next production-tree mutation. Saved archive downloads are independently compared with the local archive bytes, CRC, internal manifests and Lean build-source receipts. This batch uses Lean proofs, not new numerical experiments, for its analytic conclusions. Earlier exact finite experiments and script hashes are preserved.

All one hundred checkpoints

Each ZIP is a complete project snapshot with proof notes, verification logs, source material and restart instructions. The final ZIP includes every new Lean module and exposition. Reproducible toolchain and dependency caches are excluded.

Continue from checkpoint 247

Recover `PrimeSquares_Checkpoint_246.zip`, verify its manifest, and read `STATUS.md`, `docs/CONTINUE_HERE.md`, this report and the relevant individual proof notes. The next checkpoint is **247**.

The next mathematical priority is the exact correspondence between the new denominator/unit-indexed low symbol and the earlier rational-indexed approximation model, including exceptional-data and cutoff rounding. Then establish the source sharp high and multifrequency estimates, using the actual collar decay and square-energy machinery where applicable. Connect these proved estimates to Proposition 4.19 and ultimately Theorem 1.1. Preserve all displayed hypotheses and do not assume any of those target conclusions. The conditional global error and the new elementary low-kernel/arithmetic stages are already proved and should not be repeated.

`Checkpoints_247_346_Report.md`

Prime Squares: checkpoints 247–346

This batch contains **100 separately verified checkpoints**, adding **182 named supporting theorems in 100 modules**. The final project has **413 modules and 1503 named supporting theorems**. These are supporting declarations, not a count of completed manuscript statements.

The main advances are the exact bridge to the original rational-indexed low symbol, real cutoffs and the full conductor range; an unconditional single-scale high bound at every power below one half; and a conditional restricted-pairing bound for the actual annular von Mangoldt square kernel. **Theorem 1.1 remains open.**

The actual source low symbol

The canonical source rational set is identified exactly with the positive-denominator/unit-residue double sum. The map $u \mapsto u/q$ has its reduced numerator and denominator proved, including the denominator-one center zero. A concrete finite equivalence gives exact reindexing of complex sums and the totient cardinality identity. Induced characters, optional exceptional selectors, Gauss coordinates and real frequency shifts agree with the original source definitions.

For a real cutoff Q, integer floors enumerate the denominators only. The real Q itself stays in the smoothing widths. The ordinary width is qN^2/Q. For the exceptional conductor q_0, let $B_0 = \texttt{conductorMajorant}(q_0)$; the exceptional width is $B_0 dN^2/Q$. The contributing exceptional set is exactly

$$\{d \in \mathbb{N} : 1 \le d \le \lfloor Q \rfloor,\ B_0 d \le Q,\ q_0 d \le M\}.$$

All cutoff equality cases, natural/real conductor quotients, the exceptional minus sign and the inactive case are included. The actual induced correlation bound cancels B_0 against the exceptional width. The weighted arithmetic sum is bounded logarithmically using the previous elementary result; no PNT or Mertens assumption enters this low argument.

The inverse kernel is identified for the actual continuous circle symbol, first term by term and then for the complete sum. Exact all-real integer periodization and frequency-shift identities retain the normalizations and modulation signs. The combined ordinary-minus-exceptional model is proved equal to the original rational-indexed source low model. No desired kernel bound is assumed to obtain this identity.

The working radius may be enlarged to R^2 while the actual source denominator cap remains $\lfloor R \rfloor$. If $q_0 > R$, every exceptional selector on the source set is exactly zero and the exceptional denominator set is empty. These facts remove the intermediate exceptional-width range restriction and cover **every positive conductor**.

For natural $N \ge 2$, real $Q \ge 2$, $Q \le R$, $2R^8 \le N^2$, a positive conductor, a quadratic base character, an optional exceptional term and $\beta \le 1$, the actual source low kernel satisfies

$$|L_{N,Q}(x)| \le 2C_{\mathrm{low}} \frac{Q \log(2Q)}{N^2} \left(1 + \frac{|x|}{N^2}\right)^{-10}.$$

Its genuine all-input operator and finite-complex local estimates are

$$\|L_{N,Q}\|_{\ell^1 \to \ell^\infty} \le 2C_{\mathrm{low}} \frac{Q \log(2Q)}{N^2},$$

$$|L_{N,Q}f(x)| \le 8C_{\mathrm{low}}Q\log(2Q)\,\texttt{dyadicLocalMass}(N^2,F,|f|,x), \qquad \operatorname{supp} f \subseteq F \text{ finite}.$$

Here `dyadicLocalMass` is the exact normalized integer-shell quantity already defined in Lean. The absolute constant is constructed from the actual cutoff and arithmetic constants. Finite-indicator pairings and a genuine countable $\ell^1 \to \ell^\infty$ maximum follow, including families with varying exceptional data. The data structures record numerical and character conditions; they contain no desired norm conclusion.

The source paper budget $R^4 \le N/2$ implies the displayed geometry. For the actual source choice

$$R_{N,Q} = \max\{\exp((\log N)^{1/10}), Q^8\},$$

the low estimates therefore hold uniformly for all sufficiently large N and real $Q \ge 2$ satisfying

$$\log Q \le \frac{\min\{c/7,1\}}{8}\sqrt{\log N}, \qquad c > 0.$$

These low proofs use no new deep analytic input. The local conclusion is for finite complex inputs; the global norm conclusion is for all ℓ^1 inputs. Natural $N \ge 2$ and real $Q \ge 2$ are retained. We do not claim every domain or formulation of the printed low proposition (`p:lowcontribution`) beyond those proved hypotheses.

The actual single-scale high bound

For **every fixed** $0 < \eta < 1/2$, there is $H_\eta > 0$ such that the actual source high circle symbol and its genuine ℓ^2 multiplier satisfy

$$\sup_\theta |m^{\mathrm{high}}_{N,Q}(\theta)| \le H_\eta Q^{-\eta}, \qquad \|H_{N,Q}\|_{\ell^2\to\ell^2} \le H_\eta Q^{-\eta}.$$

This holds for natural $N \ge 2$, real $Q > 0$, $\beta \in [0,1]$, every positive conductor, every finite canonical rational set with bounded denominators, arbitrary Dirichlet-character data and source coefficients of norm at most one. The constant is independent of the denominator cap, conductor, character family and arithmetic length. The actual optional source selector satisfies the coefficient condition by a proved theorem. The uniform estimate is for the defined continuous complement `circleHighModel`, whose narrow low term retains the broad cutoff factor. Its identification with the printed low/high decomposition uses the proved source low identity and source geometry above; that identification is not asserted outside those hypotheses.

The proof is elementary relative to the already proved Gauss bounds:

1. For every $\delta < 1/2$, the principal and twisted unit Gauss sums have a uniform $C_\delta q^{-\delta}$ bound. A proved estimate also gives a universal upper bound on B_0/q_0.
2. The actual high mask is written exactly as $1 - \mathbf{1}_{q\le W}\eta(qN^2\theta/W)$, with ordinary $W = Q$ and exceptional $W = Qq_0/B_0$. Its nonzero onset and the actual annular oscillatory estimate give both size and q/W bounds.
3. Interpolation gives a centered high bound $DQ^{-\eta}q^{-(\delta-\eta)}$. The broad source cutoff is retained on both sides; no unjustified containment of broad and narrow cutoffs is used.
4. For each denominator block $s = \log_2 q$, the broad cutoffs have at most four active canonical centers. For $s \ge 2$ there is at most one; the small denominators are counted separately. Every inactive contribution is proved zero.
5. The retained factor satisfies $q^{-(\delta-\eta)} \le (2^{-(\delta-\eta)})^s$. Its geometric sum is bounded by $(1-2^{-(\delta-\eta)})^{-1}$ independently of the global denominator cap.
6. Exact three-term periodization on $[-1,1]$ passes the real sum to the circle. The resulting explicit constant is $12D/(1-2^{-(\delta-\eta)})$. Choosing $\eta < \delta < 1/2$ and discharging the Gauss and conductor budgets proves the claim.

Finite-indicator high pairings satisfy $H_\eta Q^{-\eta}\sqrt{|F|}\sqrt{|G|}$. For a sequence of actual high operators with varying cutoffs Q_j and arbitrary other allowed data, the proved condition $\sum_j Q_j^{-\eta} < \infty$ yields a genuine countable pointwise supremum in ℓ^2, with norm at most $H_\eta(\sum_j Q_j^{-\eta})\|f\|_2$. Geometric cutoffs $Q_j = 2^j Q$ satisfy this summability by a separate proved calculation.

These results do not supply the sharp printed high estimate or the fixed-cutoff countable high/multifrequency estimate. The printed factor is $Q^{-1/2}\exp((2+o(1))\sqrt{\log Q}/\log\log Q)$, which is stronger than the proved $Q^{-\eta}$ bounds. The varying-cutoff maximum has the explicit summability condition; it must not be substituted for the paper's remaining high maximal statement.

Conditional actual prime-square assembly

The remainder is defined as the actual circle high operator plus the actual global prime major-arc error operator. The annular von Mangoldt square kernel has an exact finite-input decomposition into the actual low output and this remainder output. The low input lies in ℓ^1 and the remainder input in ℓ^2; their finite coordinate agreement is checked.

The earlier conditional approximation bound gives an error norm at most

$$E_A(N,Q) = 2 \cdot 2^A Q^{-1/2}(1+\log N)^{-A}, \qquad A \geq 0.$$

The new high bound and a proved absorption $E_A(N,Q) \leq 2 \cdot 2^A Q^{-\eta}$ give an actual remainder norm $HQ^{-\eta}$ throughout the uniform source range. The **raw progression-prefix, Ren and Ghosh estimates remain explicit hypotheses** in `CircleAnalyticInputs`. That structure contains beta and coefficient conditions and those raw estimates, not the source high norm or the desired restricted pairing conclusion.

For the actual annular von Mangoldt square kernel K_N, every finite $F, G \subset \mathbb{Z}$ therefore satisfies the conditional result

$$|\langle K_N * \mathbf{1}_F, \mathbf{1}_G \rangle| \leq 2C_{\text{low}} \frac{Q \log(2Q)}{N^2} |F||G| + HQ^{-\eta}\sqrt{|F|}\sqrt{|G|}.$$

The quantifiers retain $0 < \eta < 1/2$, fixed nonnegative analytic/error parameters, a positive decay parameter c, sufficiently large natural N, the displayed real-$Q \geq 2$ logarithmic range, every positive conductor and optional quadratic exceptional data satisfying the raw analytic inputs. The bound is derived from the exact operators and their proved estimates; no scalar pairing estimate is assumed.

Remaining obligations and manuscript status

Theorem 1.1 and Proposition 4.19 remain open. This batch proves the displayed single-scale weighted-annular consequence. It does not establish the remaining sharp/fixed-cutoff high maximal or multifrequency estimates 6.16/6.21, nor silently complete the source prime-average/headline assembly. The stronger printed minor formula in Lemma 6.5 remains open; the earlier alternative minor estimate and conditional global approximation remain available.

The previously recorded ten numbered results retain their exact scopes: 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, abstract Theorem 4.1 and abstract Corollary 4.15. Lemma 3.21 retains its two explicit PNT limits. No separate PNT formalization has been integrated. The raw deep approximation inputs have not been formalized here. There is no claim of full-paper correctness or publication certification.

No new manuscript statement error has been established in this batch, so no mandatory LaTeX replacement is prescribed. The frozen manuscript, bibliography and both previously accepted source revisions are unchanged. All new work is recorded in Lean and the individual proof notes.

Verification and reproducibility

The final checkpoint passes a fresh **4020-job full build of all 413 modules and the root**, with no warnings or errors. All **1503 named supporting theorems** pass a fresh complete transitive axiom audit allowing only `propext`, `Classical.choice` and `Quot.sound`. All **415 project Lean files** pass the complete source scan: no proof placeholders, additional mathematical axioms, unchecked evaluation or unsafe code. Import and audit coverage are exact and unique.

The baseline checkpoint 246 source/artifact receipt was authenticated before any new production edits. Every new checkpoint compiled its actual new module and root and ran complete source and transitive-axiom audits. Before incremental reuse, SHA256 checks authenticated earlier Lean sources and compiled artifacts. Checkpoints **271, 296, 321 and 346** performed fresh full project builds. Logs and build receipts preserve the exact source/artifact hashes and compilation history. Scratch aggregate checks were used for proof development; they do not replace the individual production builds.

Lean 4.34.1, commit `5045d0056413266e57c625dcd7c365b10e377c52`, and Mathlib `d13f23b723b8a846827a245b89c10fc7d3f11612` remain pinned. Additional dependencies were built from that same Mathlib source. No compiler/kernel modification, dependency upgrade or mathematical axiom was introduced. The existing narrow process-executable path compatibility shim is retained solely for the container runtime. GitHub CI is configured but has not run on GitHub.

Each ZIP is written atomically after CRC testing and verification against its complete SHA256 manifest. Each checkpoint is saved before the next production-tree mutation, together with its proof notes and

the guarded stable progress-file update. Downloaded copies are independently checked for byte length, SHA256, every ZIP CRC, every manifest entry and all Lean source hashes in the checkpoint's build receipt. The final saved-files index records the resulting archive and final-document integrity checks. Lean proofs supply the new analytic conclusions; no new numerical experiment is substituted for a proof. Earlier exact numerical reports and their script hashes are preserved.

All one hundred checkpoints

Each ZIP is a complete project snapshot with the proof notes, verification logs, frozen source material and restart instructions. The final ZIP contains every new Lean module and exposition. Reproducible toolchain/dependency caches are excluded.

Continue from checkpoint 347

Recover `PrimeSquares_Checkpoint_346.zip`, verify its manifest, and read `STATUS.md`, `docs/CONTINUE_HERE.md`, this report and the relevant proof notes. The next checkpoint is **347**.

The priorities are the sharp fixed-cutoff high maximal and multifrequency estimates and their exact role in Proposition 4.19 and Theorem 1.1. The actual original real-cutoff low source identity, full-conductor low bounds, single-scale sub-half-power high norm and conditional restricted pairing are now proved in their displayed ranges and should not be repeated. Reuse the countable square-energy machinery only after establishing its actual source energy premise; a uniform single-scale norm alone does not prove a fixed-cutoff countable maximum. Keep every raw deep analytic hypothesis explicit and preserve the exact manuscript/source comparison.

`Checkpoints_347_546_Report.md`

Prime Squares: checkpoints 347–546

This batch contains **200 separately verified and preserved proof checkpoints**, adding **245 named supporting theorems in 200 modules**. The final project has **613 modules, 615 Lean files and 1748 named supporting theorems**. Supporting theorem counts do not count completed manuscript statements. **Theorem 1.1 and Proposition 4.19 remain open.**

The main results are a genuine fixed-cutoff collar maximum, including the original exceptional source term with a conductor gain and changing conductor classes; exact source decompositions locating the remaining large-denominator high terms; and a proved time-and-denominator-prefix Rademacher–Menshov principle. The sharp full high maximal estimate remains open.

What is now proved

The actual complementary narrow cutoff is analyzed at fixed real Q. For dyadic scales $N_j = 2^j M$ with natural $M \geq 2$, the first nonzero collar scale is defined exactly. Every earlier term vanishes. After onset,

the actual annular oscillatory factor has geometric decay, uniformly for arbitrary $\beta_j \in [0,1]$. Consequently its complete scalar square energy is summable and quantitatively bounded. This is a fixed-Q argument; it does not require summable varying cutoffs.

The centered continuous symbol retains the actual broad source cutoff. Exact compact circle periodization accounts for every term of its three-term window. For a single center the finite circle square energy is at most $(24q/(\pi Q))^2$. Coefficients of norm at most one may change arbitrarily with scale. The countable maximum is constructed as a genuine nonnegative real ℓ^2 function, with pointwise domination and a proved norm bound.

On each denominator block the broad source cutoffs have at most four active canonical rational centers, including the small denominators. The rational-block circle energy constant is $96bU/(\pi Q)$ for denominators at most U and coefficients at most b. A weighted finite Cauchy–Schwarz argument sums denominator-block energies without an extra block-count factor. The complete collar family with coefficient envelope $Cq^{-\delta}$ has square energy bounded by $(K_\delta Q^{-\delta})^2$ and a genuine countable ℓ^2 maximum.

The actual principal and twisted unit square Gauss sums discharge that arithmetic envelope for every $0 \le \delta < 1/2$. Ordinary and twisted characters, scale-dependent selectors and scale-dependent $\beta \in [0,1]$ are included. Exact identities identify the original ordinary high terms with this collar below their actual narrow cutoff. The original globally truncated source low family also has its proved countable $\ell^1 \to \ell^\infty$ maximum throughout the displayed uniform source logarithmic range.

For a positive exceptional conductor q_0, put

$$B_0 = \text{conductorMajorant}(q_0), \qquad W = Qq_0/B_0.$$

The exceptional collar uses W, which need not equal Q. Its canonical frequencies are exactly $0 \le r < 1$, $\operatorname{den}(r) \le \lfloor W \rfloor$ and $q_0 \mid \operatorname{den}(r)$. If $W < 1$, the set is empty. For $\eta, \varepsilon \ge 0$ with $\eta + \varepsilon < 1/2$, actual Gauss decay and conductor divisibility give

$$q^{-(\eta+\varepsilon)} \le q_0^{-\varepsilon} q^{-\eta}.$$

The already proved uniform bound on B_0/q_0 then yields actual exceptional collar energy at most

$$(H_{\eta,\varepsilon} Q^{-\eta} q_0^{-\varepsilon})^2,$$

and the corresponding genuine countable maximum. This covers every $Q > 0$. The source global-radius restriction is identified exactly with a bounded coefficient mask, so no artificial requirement $W \le R$ remains. Inactive exceptional data and conductors beyond the source radius give exactly zero exceptional collar.

For changing characters, the displayed numerical classification premise is

$$q_0(i) \ge 2^i.$$

This is a **hypothesis on the family of conductors**, not a formalized Landau–Page zero theorem. With exactly one class selected at each dyadic time, finite times are partitioned by the selected class. The squared class constants sum geometrically. There is no assumption that the selected class is monotone or stays active on a common tail.

Combining the ordinary and exceptional contributions proves a genuine maximum for the **signed original source collar** for every $0 \le \eta < 1/2$:

$$\left\| \sup_j |C_{N_j,Q} f| \right\|_2 \le K_\eta Q^{-\eta} \|f\|_2.$$

Here $Q \ge 1$, $M \ge 2$, the source radii satisfy $Q \le R_j$, the active flags and character data can vary, $\beta \in [0,1]$, and the conductor-class condition above is retained. The Lean witness equals the pointwise countable supremum and dominates every individual output. Finite-indicator pairings have the corresponding $K_\eta Q^{-\eta}\sqrt{|F|}\sqrt{|G|}$ bound.

The continuous source model uses the already formalized broad-times-narrow low cutoff. Its identification with the printed cutoff-difference decomposition retains the earlier source geometry and exact low-symbol bridge. The extended symbol estimates at smaller nonnegative radii, where allowed by their Lean signatures, do not assert that printed-source identification.

This controls the collar contribution only. It does not establish the sharp full high bound $Q^{-1/2}\exp((2+o(1))\sqrt{\log Q}/\log\log Q)$, the remaining large-denominator maximum, or the headline theorem.

Prefix theorem and proposed proof repair

A checked two-denominator example shows that a source-radius cutoff in one denominator block need not be one common time tail: denominators 2 and 3 at radii 2 and 3 have activation rows $(1,0)$ and $(1,1)$. Each individual denominator does have a tail under increasing radii. The full block is a denominator prefix. Exact finite identities prove the natural/real cutoff floors and the rational grouping by denominator, including the genuine circle major-arc model and exceptional denominators $q_0 d$.

A finite binary tree argument now proves the Rademacher–Menshov prefix step. Every scalar prefix square is bounded by $(h+1)$ times the actual binary-tree energy. The associated square-root envelopes are constructed in real ℓ^2, with exact spatial-total and norm identities. Uniform interval norm budgets give a logarithmic $(h+1)$ prefix norm cost. The orthogonal ℓ^2 specialization is fully discharged. A second version dominates **every time and every denominator prefix simultaneously**, from explicitly displayed interval maximal majorants and their norm budgets.

The paper's underlying multifrequency interval estimate, its transference and its full source application are still open. They are not introduced as axioms or silently replaced by the prefix conclusion.

The proposed repair to the proof of Proposition 6.21 replaces the common-tail step by the manuscript's existing Corollary 6.19 (`c:orlicz-prefix`). The ordinary factor becomes $(1+s)^2$, and the exceptional large-denominator factor becomes $(1+\log(q_\chi d))^2$. These add only fixed logarithmic powers. The exact sharp-exponent absorption is proved in Lean: for every $\epsilon > 0$ and fixed natural n, uniformly for $Q > 0$ and $\log Q \geq 2$,

$$Q^{-1/2}(1+\log Q)^n \exp\left(2\frac{\sqrt{\log Q}}{\log\log Q}\right) \leq D_{n,\epsilon} Q^{-1/2}\exp\left((2+\epsilon)\frac{\sqrt{\log Q}}{\log\log Q}\right).$$

The replacement changes a proof justification, not the stated conclusion. It is saved separately as `proposed_revisions/Replacement_6_21_Denominator_Prefix.tex`; the frozen manuscript and both previously accepted revisions are unchanged. It remains a proposed local repair, not a certificate of the entire proposition.

Exact frontier and remaining work

The original source high symbol is identified exactly as

$$\text{High} = \text{signed collar} + \text{ordinary large denominators} - \text{exceptional large denominators}.$$

The final continuous-symbol, genuine ℓ^2 operator and finite-complex-input convolution identities retain this split. The annular von Mangoldt square convolution is exactly low plus signed collar plus the large-denominator remainder plus the genuine major-arc error. The low input lies in ℓ^1 and the other inputs in ℓ^2, with the finite coordinate agreement checked. No bound on a remaining term is inserted into an identity.

The next substantial task is the actual source multifrequency interval estimate and its large-denominator maximal application, followed by the sharp full high/source endpoint assembly in Proposition 4.19 and Theorem 1.1. The printed minor estimate in Lemma 6.5 also remains open in its stronger form; the earlier alternative estimate and conditional global approximation remain available.

The ten previously recorded numbered results retain their exact scopes: 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, abstract Theorem 4.1 and abstract Corollary 4.15. Lemma 3.21 still has its two explicit PNT limits. No separate PNT formalization was integrated. Raw progression-prefix, Ren and Ghosh approximation inputs remain explicit hypotheses where consumed. This batch introduces no new deep analytic axiom and no full-paper or publication-correctness claim.

Verification, saving and recovery

The final checkpoint passes a fresh **4220-job full project build of all 613 modules and the root**, with no warnings or errors. All **1748 named supporting theorems** pass a complete fresh transitive axiom audit allowing only `propext`, `Classical.choice` and `Quot.sound`. All **615 Lean files** pass the complete source scan: no placeholders, added mathematical axioms, unchecked evaluation or unsafe code. Root imports and theorem-audit coverage are exact and unique.

Baseline checkpoint 346 was authenticated before the first production edit. Every new checkpoint compiled its own actual new module and root and ran the full source and transitive-axiom scans. Incremental reuse authenticated all earlier source and compiled-artifact hashes. Fresh full project builds were performed at **371, 396, 421, 446, 471, 496, 521 and 546**. Aggregate scratch checks were used for development and do not replace those individual production builds. A read-only copy of authenticated old compilation objects was used solely for prototype checks during subsequent clean builds; it is excluded from the deliverable and does not affect production verification.

Lean 4.34.1, commit `5045d0056413266e57c625dcd7c365b10e377c52`, and Mathlib `d13f23b723b8a846827a245b89c10fc7d3f11612` remain pinned. No compiler/kernel modification or dependency upgrade was made. The existing narrow executable-path compatibility shim remains solely for this container runtime. GitHub CI is configured but has not run on GitHub.

Each archive is atomically packaged after CRC and complete SHA256-manifest checks. Every checkpoint is preserved before the next production mutation. Saved archive readbacks are checked for exact bytes, SHA256, every ZIP CRC, every manifest entry and the Lean source hashes in their authenticated build receipts. Readback completion is recorded separately after the final save; the extended checkpoints-347–600 saved-files index covers this entire batch and the subsequent continuation.

One save exception is explicit: checkpoint **352** passed every Lean/build/audit/package check, but its original standalone save response timed out and remained unconfirmed. That unknown write was not retried. Its exact archive and notes were instead preserved inside the distinct, confirmed checkpoint **353** archive, independently downloaded and fully integrity-verified there, and included again under `recovery/checkpoint352/` in final checkpoint **546**. Thus all 200 checkpoints are separately recoverable; the count must not be described as 200 confirmed standalone archive uploads. Checkpoint 372's later response timeout was reconciled by authoritative saved-file records and exact verified downloads of all three committed files, without repeating the write. Checkpoint 484's interrupted save was likewise reconciled by exact verified downloads of all three committed files, including progress version 482, with no repeated write. Checkpoint 416's discovery failure occurred before any upload-preparation request was issued; the guarded helper invocation then succeeded. The records distinguish these cases without fabricating success receipts.

No new numerical experiment is substituted for the new analytic proofs. Earlier exact numerical reports and their script hashes are retained; the new finite activation counterexample itself is proved in Lean.

All two hundred checkpoints

Each archive is a complete source project snapshot with proof notes, frozen source, current verification logs and continuation instructions. Starting at 485, redundant historical build receipts are hash-indexed instead of duplicated; their original archives and the working project retain them. Current build receipts, audits and every proof source remain included. The final ZIP contains all 200 new modules and expositions. Toolchain and dependency caches are reproducible and excluded.

Continue from checkpoint 547

Recover `PrimeSquares_Checkpoint_546.zip`, verify `verification/SHA256SUMS.txt`, and retain the separately saved files index alongside it. The final save receipt is issued after packaging. On a restart without the recorded compilation cache, perform a fresh full build to initialize new artifact receipts. Read `STATUS.md`, `docs/CONTINUE_HERE.md`, this report and the relevant proof notes. The next checkpoint is **547**. Reuse the completed fixed-Q ordinary and exceptional collar energy, actual changing-character collar maximum, exact source-radius prefix identities and proved abstract prefix theorem. Prove the actual multifrequency interval premise and large-denominator maximum next; do not repeat completed collar work or infer a full high maximum from a uniform single-scale norm.

`Checkpoints_347_600_Report.md`

Prime Squares: continuation through checkpoint 600

Checkpoint 484 is reconciled, and the project has continued through checkpoint 600. All three original checkpoint-484 saves were confirmed by authoritative records and exact verified downloads; its write was not repeated. Checkpoints 485–600 then each compiled their actual new proof module and root, passed the complete source and transitive-axiom audits, and were separately preserved before the next production mutation.

The current project has **667 project modules, 669 Lean files and 1807 named supporting theorems**. Across checkpoints 347–600 this is **254 proof units and 304 added named supporting theorems**; the new extension 547–600 adds **54 modules and 59 supporting theorems**. These counts are not counts of completed manuscript statements. **Theorem 1.1, Proposition 4.19 and the sharp full high maximal estimate remain open.**

What this continuation establishes

The earlier checkpoints complete the fixed-Q ordinary and exceptional collar estimates, including the signed original source collar, its conductor gain and changing-character conductor classes. They also prove the abstract time-and-prefix Rademacher–Menshov principle and exact source denominator-prefix identities. The separately saved checkpoints-347–546 report explains those results and the proposed local repair to Proposition 6.21.

The extension 547–600 connects that prefix principle to the actual circle and integer Fourier multipliers:

- Circle multiplication and the integer multiplier action respect symbol products. Almost-everywhere circle representatives are handled explicitly.
- Pointwise disjoint continuous symbols give exactly orthogonal integer l2 outputs, even for different inputs. Finite sums and intervals have exact Pythagorean square-energy identities.
- Arbitrary complex weights preserve spectral disjointness; bounded weights have the displayed square-budget comparison.
- Finite lists are padded by exact zeros to a binary capacity. Padding changes neither their genuine prefixes nor their square budget. The depth is Nat.clog 2 L, proved at most Nat.log2 L+1, including L=0 and L=1.

- For a finite disjoint family m_i, one nonnegative real l2 function dominates every nonnegative real denominator cutoff. Its norm is at most (Nat.log2 L+2) times the square root of the exact output energy. If the symbols are bounded by A, the energy is at most A^2 times the input square norm, with no cardinality loss.
- An exact localizer identity m_i=m_i*p_i and disjoint localizers imply all off-diagonal products vanish and every interval symbol localizes to the sum of its own localizers. No unjustified assertion that a smooth localizer is an idempotent projection is made.
- Explicit interval majorants and localized norm budgets yield a true majorant over every time and every denominator prefix. A separate sufficient criterion constructs those interval witnesses from finite time square-energy bounds on the actual circle symbols. **Those frequency-energy bounds are hypotheses of the criterion, not established properties of the paper's full high family.**
- Rational symbols are grouped exactly by denominator. The original high and exceptional high source symbols retain their actual formulas in these identities.
- A band Q<den<=R is exactly the difference of prefixes at R and min(Q,R). Thus the band is correctly empty when Q>R, including conductor-dependent exceptional cutoffs. A single prefix witness controls every such difference with norm cost two.
- The interval-to-prefix bridge reaches actual capped source high operators with varying scales, characters, conductors and beta. A fixed cap M applies to the entire source set only when 0<=R<=M; this cap restriction is proved and retained. No maximum over all unbounded caps is inferred from it.
- The already proved signed collar maximum is reused in an exact reduction of full original source high control to a supplied majorant for its remaining large-denominator remainder. This exposes the missing input instead of certifying it. A finite test-set pairing lemma also assembles the genuine low, collar, remainder and major-arc error contributions with each bound displayed separately.

A verified guard against an invalid maximal inference

The final four checkpoints prove a general obstruction using the existing actual Fourier convention. For j>=0, the continuous symbol exp(-2*pi*i*j*theta) defines an integer multiplier of operator norm at most one and sends the unit mass at zero exactly to the unit mass at j. Any real l2 majorant for the first N such outputs must have square norm at least N. Hence no real l2 function dominates the countable family on this one fixed input.

This is **a counterexample to the general inference from uniform individual operator bounds to a countable maximal bound**. It is not a counterexample to the manuscript theorem. It explains why the separate multifrequency/maximal argument is essential and cannot be replaced by the single-scale high estimate already proved.

Exact mathematical frontier

Proved: the signed source collar has a genuine fixed-Q countable l2 maximum K_eta Q^(-eta) for every 0<=eta<1/2, with Q>=1, dyadic starting scale M>=2, source radii R_j>=Q, beta in [0,1], and the explicit conductor-class condition q0(i)>=2^i. Character data and active flags may vary. That numerical conductor classification is a hypothesis; a Landau–Page zero classification is not claimed. Earlier exact source geometry and the broad-times-narrow low-symbol bridge remain required when identifying the continuous source model with the printed decomposition.

Proved with explicit hypotheses: the abstract and actual-multiplier interval-to-prefix principles, disjoint/localized spectral criteria, finite-cap source high bridge, and final assembly lemmas. Their source interval-energy or interval-majorant premises remain visible. These conditional results are not counted as completed numbered source conclusions.

Still required: the actual source multifrequency interval estimate, its needed transference and beta range, the remaining large-denominator high maximum, and the sharp full high/source endpoint assembly leading to Proposition 4.19 and Theorem 1.1. The stronger printed Lemma 6.5 estimate also remains open in the scope previously recorded. Single-scale high power decay and the completed collars do not close those gaps.

The ten previously recorded numbered results retain their scopes: 3.1, 3.11, 3.12, accepted revised 3.14 and Corollary 3.16, original 3.20, 3.24, 3.27, abstract Theorem 4.1 and abstract Corollary 4.15. Lemma 3.21 retains its two explicit PNT limits. A separate PNT formalization was not integrated. Published Ren/Ghosh estimates and the progression-prefix input remain explicit raw hypotheses where used. This continuation adds no deep theorem axiom.

The proposed proof-step repair in proposed_revisions/Replacement_6_21_Denominator_Prefix.tex remains separate: source-radius activation is a denominator prefix, so the prefix corollary supplies the extra fixed logarithmic factor. The checked polynomial absorption preserves the 2+epsilon sharp expo-

nent in its displayed range. This is a proposed local repair, not a full certificate of Proposition 6.21. The frozen manuscript and both accepted revisions are unchanged; no further mandatory source replacement is established here.

Verification and preserved files

The final checkpoint passes a fresh **4274-job full project build of all 667 modules and the root**, with no warnings or errors. All **1807 named supporting theorems** pass a fresh complete transitive axiom audit permitting only propext, Classical.choice and Quot.sound. All **669 Lean files** pass the source scan. There are no proof placeholders, added mathematical axioms, unsafe code or unchecked evaluation. Exact root-import coverage, unique named-theorem coverage, frozen manuscript hashes and the existing numerical-report script hashes are checked.

Every individual checkpoint compiles its new actual module and root, with remote project artifact-cache reuse disabled. Unchanged proof-source and compiled-artifact hashes are authenticated before incremental reuse. In this extended sequence full builds occur at 371, 396, 421, 446, 471, 496, 521, 546, 571, 596 and 600. Aggregate development checks are useful preparation and are not individual production completion certificates.

Lean 4.34.1, commit 5045d0056413266e57c625dcd7c365b10e377c52, and mathlib d13f23b723b8a846827a245b89c10fc7d3f11612 remain pinned. No compiler/kernel alteration or dependency upgrade was made. The narrow existing executable-path compatibility shim is only for this container runtime. Configured GitHub CI has not run on GitHub.

Each ZIP is atomically packaged and checked against every ZIP CRC and every included SHA256 manifest entry. Starting at checkpoint 485, only redundant historical build-receipt copies are omitted from new ZIPs and indexed by exact hash in verification/ARCHIVED_RECEIPTS.json; their original checkpoint archives and the working project retain them. Every proof source, the complete current build receipt and all current audits remain included. This reduces repeated archive size without changing proof verification. Reproducible toolchain and dependency caches are excluded.

Saved archive verification downloads the committed files and compares their byte lengths/SHA256, all ZIP CRCs, archived manifest entries and current build-receipt source hashes. The final readbacks occur after the final archive save. The separately saved index is created only after all 254 checkpoint recoveries have passed those checks; consult that index for completed readback coverage, per-file save identities, final progress version and the exception below. Retain that index alongside the final ZIP, because the final checkpoint's own save receipt is issued after packaging.

One earlier save exception remains explicit: checkpoint 352 passed Lean, audit and package checks, but its original standalone save outcome remained unconfirmed after a timeout. That write was never retried. Its exact standalone ZIP and notes were preserved inside confirmed checkpoint 353, independently recovered and fully checked there, and included again under recovery/checkpoint352 in checkpoints 546 and 600. Thus there are **253 confirmed standalone archive saves plus one exactly recovered checkpoint**, not 254 confirmed standalone uploads. Checkpoint 372 and the interrupted checkpoint 484 were each fully reconciled by exact verified downloads of all three committed files without repeated writes. Checkpoint 416's read-only discovery failure occurred before any upload request and was safely retried at the save step only. A later monitoring-session interruption left checkpoint 590 staged before any output package or upload request. Its new module and root were forced to rebuild, all audits reran, and its first save then succeeded; no source restaging or repeated write occurred.

The early working-draft bundles are restart aids with explicit uncompleted-draft labels. They are not substitutes for the later individually verified checkpoint ZIPs. No numerical sampling substitutes for these new Lean arguments; the finite activation obstruction and the final Fourier-multiplier obstruction themselves are proved in Lean.

Checkpoints 347–600

Checkpoint	Mathematical unit	Added supporting theorems	Project total	Build	Archive and exposition
347	Exact dyadic annular scale arithmetic	3	1506	incremental	ZIP / Proof notes
348	Exact dyadic growth and positivity of the narrow collar widths	2	1508	incremental	ZIP / Proof notes

Checkpoint	Mathematical unit	Added supporting theorems	Project total	Build	Archive and exposition

Restart and next proof task

Use PrimeSquares_Checkpoint_600.zip and Saved_Files_Index_347_600.json. Verify verification/SHA256SUMS.txt, then read STATUS.md, docs/CONTINUE_HERE.md and this report. Restarting without the recorded compilation cache requires a fresh full build to create new artifact receipts; do not present an old cache receipt as evidence for newly generated binaries. The next checkpoint is **601**.

Focus the next mathematical milestone on the actual source multifrequency interval estimate and the large-denominator high maximal bound. Reuse the completed collars, prefix machinery and exact source identities. Keep raw deep external hypotheses distinct from own-paper targets and verify any published external theorem's precise primary-source statement before importing it as an allowed hypothesis. Theorem 1.1 remains an explicit eventual goal.

Earlier plans and completion notes

archive/PAPER_COMPLETION_Pre1265.md

Completion of the reviewed corrected paper

The internal formalization is complete within the agreed conditional scope. The complete inventory has 54 numbered theorem, proposition, lemma and corollary targets and four definitions. There are 22 claims proved under ordinary source hypotheses, 31 complete implications from explicit independent inputs, one quoted external theorem, and no open internal numbered endpoint. The four definitions are formalized. These counts measure statement coverage and are not proof-completion percentages.

Main result	Current checked evidence	Scope
Theorem 1.1	theorem_1_1, theorem_1_1_restricted, theorem_1_1_strong_real	Complete conditional improving estimates for the actual averages and source normalization
Theorem 1.3	theorem_1_3, theorem_1_3_endpoint, theorem_1_3_open_pq	Complete conditional sparse domination, endpoint and open triangle
Theorem 1.5(i)	theorem_1_5_i	Complete conditional persistent universal L1 badness
Theorem 1.5(ii)	theorem_1_5_ii_closed_signed_maximal	Complete conditional near-L1 ergodic maximal estimate; signed maximal input proved internally
Theorem 7.2	theorem_7_2_closed_signed_maximal	Complete conditional three-family quantitative Orlicz theorem
Corollaries 7.6 and 7.46	corollary_7_6_closed_signed_maximal, corollary_7_46_closed_signed_maximal	Complete conditional Lp maximal, transfer and convergence conclusions
Quantitative Goldbach theorem	goldbach_section9_headline_complete	Complete conditional estimate at all sufficiently large real cutoffs, with arithmetic criterion and smooth seed proved internally

The current continuation proves the general finite signed-sum maximal theorem at constant 6. Its binary bound holds for every exponent at least one, including all finite lengths and extended norm bounds. Exact Boolean-sign averaging and the Lp triangle inequality replace its former independent hypothesis. The public Section 7 and near-L1 exports consume this proof. The prior primitive two-square criterion, W(alpha) integrability for every alpha>1 and concrete smooth seed remain proved and integrated.

The paper-wide audit independently checks every declared theorem-like environment type, all source labels and statement hashes, all four definitions and all current evidence anchors. Lean prints the exact types of those declarations. The audit verifies removal of the signed maximal hypothesis from the four public exports and of the primitive criterion from the current Section 9 arithmetic/headline exports. Source scans, authenticated compilation receipts and complete transitive axiom audits cover the proof files. The only allowed foundational axioms are propext, Classical.choice and Quot.sound. Numerical experiments remain supplementary and are not Lean proofs; unchanged verified probes are preserved without redundant reruns.

Independent general inputs remain unproved, including the PNT/progression, Ren/Ghosh, multifrequency, IW/sampling, general real-variable and ergodic, Weil, and general sieve/Mertens/effective mean interfaces. Their exact scopes and still-unproved formulation bridges are listed in INDEPENDENT_INPUTS_CURRENT.md and the proof registry. This is a partial formalization of the mathematics used by the paper, with complete own-paper deductions in the agreed scope. An axiom audit does not establish the truth of explicit input hypotheses. The quoted Granville–Kurlberg theorem is external and optional for the badness conclusion.

The completeness target is the selected full source plus the explicitly supplied corrected Section 11 presieving statement. The weaker original presieving statement is not claimed. The user is applying manuscript edits; application is pending verification against a revised upload. No original source file is changed and no additional replacement passage is needed from this continuation. Stronger unnumbered assertions in alternative proof routes retain their separate documented scopes.

See blueprint/Paper_Proof_Status.json and blueprint/Paper_Proof_Status.csv for exact per-statement evidence. verification/paper-completion-current.json records the final coverage checks; verification/paper-declaration-types-current.log records the actual Lean types. Read docs/Remaining_Work_Plan.md for

source synchronization and the separately optional independent-input projects.

archive/Pre1264_SECTIONS_3_TO_8_REVIEW.md

Sections3–8 review at checkpoint1114

No reviewed current-paper statement in Sections3–8 remains partial or open within the agreed conditional scope. The explicitly quoted general external theorems remain unproved. This is not an unconditional formalization of all mathematics used by the paper.

The two previously incomplete standalone statements are now complete conditional implications. The corrected prime-square input is source_corrected_prime_square_input: one fixed-level genuine optional Page datum per N precedes Q, the full q<=R^(11/10) major range is proved, and the complementary R^(-1/4)*(log N)^d minor bound and required uniform thresholds are proved. The general fixed-level uniform progression theorem and raw Ren/Ghosh estimates remain unproved independent inputs.

The complete quantitative IW proposition is proposition_quantitative_IW_full: one common construction at every real Q>=2^k, the literal parameters, all rational fraction points, rough full-Lp multiplier norm, both full-space sampling directions, unique interpolation and arbitrary finite-dimensional normed complex Shannon targets for every 1<=p<=infinity. General Tao construction, full IW/sampling statements and their explicitly recorded general bridges remain unproved. Read FULL_QUANTITATIVE_IW_COMPLETION.md and FULL_IW_EXTERNAL_BOUNDARY.md for the exact boundary.

All earlier sparse, multifrequency, fixed-measurable-symbol denominator, maximal, Orlicz and Section8 scopes retain their reviewed statuses and their own hypotheses. The corrected cyclic Fourier model uses only denominators dividing P; its declared correction was rebuilt and audited before final completion credit.

The exact latest upload is preserved. It has all eight closed-L corrections and the corrected minor statement, but its approximation proof still uses the removed stronger minor estimate. The selected copy restores the already supplied approximation passage, the accepted dyadic factor-four application and preferred upper-cutoff wording, retaining all upload labels. The complete upload-to-selected patch is saved; the user's local manuscript is not edited remotely. See SOURCE_UPDATE_1107.md.

The next mathematical work is the five mapped Section10/11 circle-method, sieve, main-term and normalized integral estimates. Their own conclusions are internal proof obligations. The Section9 arithmetic/final-count deductions are already checked; their use of the classical primitive two-square criterion remains explicitly conditional. The headline Goldbach theorem remains open.

Source-only revision1 after checkpoint1114 supplies one complete approximation proof with explicit major and complementary minor cases, and removes a stray editing instruction in the earlier saved TeX. Every numbered statement, label, Lean source and compiled artifact is unchanged. See APPROXIMATION_PROOF_REVISION_1114_1.md.

archive/Pre1264_SECTION_11_PLAN.md

Remaining Section11 work after checkpoint1230

Completed in the agreed conditional scope: fixed-sieve comparison, local densities, corrected presieving, full lower-sieve application, uniform actual main-term size, arbitrarily large common cutoff and finite lower exception deductions. The main-term exponent A0/2+6 is independent of C. No new deep input was introduced in this continuation.

Four substantive source claims remain:

1. l:wumatomakisum: weighted upper main-term comparison, including smoothing/integration and the normalized constant.
2. p:sieveneedupper8: full upper application over the actual multiplier set.
3. l:numericalcomparison: strict normalized comparison with the upper sieve constant.
4. t:repmotthm: final Goldbach assembly.

The original weaker presieving statement remains separately open pending manuscript synchronization; its corrected conditional variant is proved. The user is editing the compact replacements. The manuscript is unchanged. Minor A/A0 notation fixes are saved in blueprint/Section11_LowerBound_Notation_Fixes.tex.

The ledger has19 proved,29 complete conditional implications,1 quoted external theorem and5 open claims, plus4 definitions. No checkpoint or supporting-theorem percentage is claimed. Read SECTION_11_LOWER_BOUND_COMPLETION.md and EXTERNAL_SIEVE_INPUTS.md.

archive/Pre1264_SECTION_11_REMAINING_WORK.md

archive/Pre1264_SECTION_7_SIGNED_MAXIMAL_BOUNDARY.md

General finite signed-sum maximal boundary

Checkpoint 904 records `RawFiniteSignedMaximalInput C`. This is a general finite-sequence consequence of Rademacher-Menshov and scalar Khintchine, uniform for 1<=p<=2. It ranges over arbitrary complex sequences u_j(x) on integer counting measure, arbitrary finite length J and arbitrary extended norm bound B. If every complex signed sum with |sigma_j|<=1 has actual Lp membership and norm at most B, the maximum of all partial sums through J has actual Lp membership and norm at most C log(2+J) B. No Fourier symbol, arithmetic data, cutoff, annular kernel, IW construction or current-paper maximum occurs in its fields.

Its general existence is not proved in Lean and it is not a Lean axiom. The boundary includes the deterministic dyadic decomposition, scalar Khintchine, Fubini and the Lp triangle inequality. A primary source for the decomposition is Mirek, Stein and Zorin-Kranich, *A bootstrapping approach to jump inequalities and their applications*, Lemma 2.5, equation (2.7), https://arxiv.org/pdf/1808.09048 . Scalar Khintchine and its function-valued Fubini consequence are also recorded in Tao's *Lecture notes 4 for 247A*, Corollary 5.8, https://www.math.ucla.edu/~tao/247a.1.06f/notes4.pdf .

For clarity, the quantitative consequence is obtained by padding to a power of two and grouping increments in dyadic intervals at each level. Choosing one random sign per disjoint interval produces a permitted signed sum of the original u_j. Khintchine's lower bound at exponent 1, followed by monotonicity of probability Lp norms, bounds the square function uniformly for 1<=p<=2. The deterministic inequality and the Lp triangle inequality then give the number of levels, which is bounded by a universal multiple of log(2+J). This general argument remains in the explicit unformalized input, rather than being counted as a Lean proof.

The paper-specific signed sums are proved for the actual IW annular operators, with exact identities and K*r*C_(r,k) bounds. Their instantiation of this general theorem, and adding the checked initial term, are separate checked deductions. The entire low maximum, its narrow large-scale sampling argument, and the restricted maximal estimate are never external inputs.

Original LaTeX source fragments

Section11_LowerBound_Notation_Fixes.tex

```
% Minor notation fixes only; not applied to the selected manuscript.
% In e:H1elementary10, replace
%   \gg_A N(\log N)^{-A/2-2}
% with
\gg_{A_0} N(\log N)^{-A_0/2-2}

% In the proof of l:maintermsize8, replace
%   Taking \(C\) sufficiently large in terms of \(A\)
% with
Taking \(C\) sufficiently large in terms of \(A_0\)
```

Section11_Presieving_Replacements.tex

```
% Proposed replacements for l:presieving. The selected manuscript is unchanged.
% 1. Replace the passage beginning "Let \(2\leq R<z\)" and ending
% with the displayed condition \log D_0/\log R\longrightarrow\infty by:

Assume \(X\geq0\) and \(g(1)=1\).
Fix constants \(C,A>0\), put
\[
 R=(\log N)^C,\qquad
 D_0=\exp((\log\log N)^3),\qquad D_1=D/D_0,
\]
and work with sufficiently large \(N\). Assume
\[
 R+1\leq z\leq D_1\leq N^A,\qquad D_0<D.
\]
Write
\[
 \mathfrak P_0=\{p\in\mathfrak P:p\leq R\},\qquad
 \mathfrak P_1=\{p\in\mathfrak P:R<p<z\}.
\]
Suppose that there are fixed constants
\(\kappa_0,\kappa>0\) and \(K_0\geq2\), uniform in the sequence and
its density function, such that for every \(2\leq w<y\leq z\),
\begin{align}\label{e:tworangesievedimension}
 \prod_{\substack{w\leq p<y\\p\in\mathfrak P_0}}
 (1-g(p))^{-1}
 &\leq
 \left(1+\frac{K_0}{\log w}\right)
 \left(\frac{\log y}{\log w}\right)^{\kappa_0},\notag\\
 \prod_{\substack{w\leq p<y\\p\in\mathfrak P_1}}
 (1-g(p))^{-1}
 &\leq
 \left(1+\frac{K_0}{\log w}\right)
 \left(\frac{\log y}{\log w}\right)^\kappa.
\end{align}
All asymptotic assertions below are uniform when these constants are fixed.

% 2. In the first display of the proof, replace the definition of s_0 by:

\[
 s_0=\frac{\log D_0}{\log(R+1)}.
\]

% In the accompanying application of the preliminary coefficient theorem,
% use sifting limit R+1 on the prime set P_0. It includes exactly all primes
% p<=R, also when R itself is prime. The outer sifting limit remains z.
% Replace the subsequent large-s_0 justification by the following passage.

Apply the general Rosser--Iwaniec coefficient theorem to
\(\mathfrak P_0\), level \(D_0\), and sifting limit \(R+1\).
Its coefficient estimates and the decay of the sieve functions and error
majorant give constants \(c,C'>0\), depending only on the fixed sieve
parameters, such that
\[
 \left|\sum_e\lambda_{0,e}^{\pm}g(e)-V_0(R)\right|
 \leq C'V_0(R)e^{-c s_0}
\]
for sufficiently large \(N\). Since
\[
 s_0=\frac{(\log\log N)^3}{\log((\log N)^C+1)}
 \gg_C(\log\log N)^2,
\]
the relative preliminary error is smaller than every fixed negative
power of \(\log N\). The condition \(z\leq D_1\) places the outer
sieve in its stated range \(s\geq1\), and \(z\leq N^A\) permits this
preliminary error to absorb the logarithmic losses from the outer
coefficient sum. The signed coefficient construction in the remainder
```

```
of the proof is unchanged.

% 3. Strengthen the Mertens justification preceding l:presieving by adding
% the following passage. A coarse implied-constant estimate by itself
% does not supply the refined dimension hypothesis above.

We use the uniform interval forms of Mertens' theorem: for a suitable
constant \(K\) and every \(2\leq w<y\),
\begin{align*}
 \prod_{\substack{w\leq p<y\\p\equiv3\; (\mathrm{mod}\;4)}}
 \left(1-\frac1{p-1}\right)^{-1}
 &\leq
 \left(1+\frac K{\log w}\right)
 \left(\frac{\log y}{\log w}\right)^{1/2},\\
 \prod_{\substack{w\leq p<y\\p>2}}
 \left(1-\frac1{p-1}\right)^{-1}
 &\leq
 \left(1+\frac K{\log w}\right)
 \frac{\log y}{\log w}.
\end{align*}
Restricting these products to the relevant outer prime sets only
decreases them. For the preliminary prime sets, the local bounds
\(g(p)\leq2/(p-3)\) for \(p\geq7\), together with the bound
\(g(5)\leq1/2\) when that prime occurs, give the refined dimension
bound with \(\kappa_0=2\) and a uniform constant. Thus only the outer
dimensions \(1/2\) and \(1\) determine the final sieve functions.

\vspace{12pt}
\textbf{What has been done.} This package contains a first dependency blueprint for the
attached 96-page manuscript and a small Lean project. The project formalizes finite
exceptional-set inequalities, elementary arithmetic used in the paper, and positivity
of the elementary bracket in the last sieve comparison. These are useful components
of a larger development; none is a formalization of a headline theorem of the paper.

\textbf{What this document does not claim.} It is not an expanded proof of every lemma,
and it is not a certificate for the whole paper. In particular, the circle-method
approximation, high--low estimates, stopping-time proof, Ionescu--Wainger argument,
ergodic divergence argument and sieve estimates remain to be encoded and checked.
The word \emph{target} below always denotes unfinished work.

\textbf{Source lock.} Numbering and page references refer only to the uploaded file
\lean{Prime_Squares (32)(1).pdf}. Its SHA-256 is recorded in
\lean{PROVENANCE.json}. A revised manuscript must be compared with this snapshot
before the paper-to-Lean map is reused.

\textbf{Reproducibility.} Lean is pinned to 4.34.1. Mathlib is pinned to commit
\lean{d13f23b723b8a846827a245b89c10fc7d3f11612}. The source archive includes a lockfile,
the Lean modules, build instructions and scripts for checking proof dependencies.
The verification logs, rather than this prose, record what was actually run.
```

\textbf{Reading route.} Sections 1--3 define the scope and targets. Sections 4--5 give complete mathematical explanations of the checked components. Sections 6--11 map the unfinished arguments. Sections 12--14 record imports, audit points and the next inputs needed. The appendix inventories numbered statements in the attached PDF.

\section{The trust boundary}
There are three different objects in a formalization project.
\begin{enumerate}
\item A \textbf{blueprint} specifies mathematical objects, statements, dependencies and proof steps. It is written for humans and can itself contain mistakes.
\item A \textbf{Lean proof} is an actual term accepted by Lean's kernel. Elaborating a statement containing a placeholder is not the same as proving it.
\item A \textbf{conditional formalization} proves a result from explicitly declared external statements. Its mathematical scope depends on the accuracy and consistency of those statements as well as on the translation of the final theorem.
\end{enumerate}

For the present starter, no extra analytic-number-theory axioms are declared. Theorems in the starter have explicit hypotheses for the errors and main terms they use. Those hypotheses are not assertions that the required analytic estimates have already been established for prime squares.

For the completed project it is reasonable to import deep published results. Each import should have one stable declaration, a precise source, the full range of parameters, and a statement of constant dependence. The project should continue to prove the new arguments of this paper. Assuming its own high--low estimate or its final sieve comparison would leave that part of the paper unverified.

An axiom audit must examine the \emph{transitive} dependencies of each headline theorem, not just count explicit occurrences of \lean{axiom}. Standard Lean/Mathlib dependencies can include \lean{propext}, \lean{Classical.choice} and \lean{Quot.sound}. An unfinished proof introduces \lean{sorryAx}. The starter's scripts reject unapproved dependencies and scan the project sources for proof placeholders and new axioms.

\subsection*{What the Hua example establishes}
The supplied Hua blueprint contains both a current-paper development and substantial material from an earlier, broader draft. Its total length is therefore not a useful measure of how long the prime-squares blueprint should be.

At the repository snapshot inspected for this request, the trusted external declarations are \lean{Hua.siegel_walfisz} and \lean{Hua.hua_theorem10}. The second is an exponential-sum estimate, rather than the statement that sufficiently large admissible integers are sums of five prime squares. A static scan of its default library closure passed. That scan does not replace an independent rebuild or an audit of the meanings of its axioms and headline statements. This starter does not import that repository.

\page
\section{Objects and final statements to encode}
\status{Specifications only; the headline statements are not yet Lean declarations}

Use natural numbers for prime parameters and integer indices for discrete functions. Define, for \(N\ge2\),
\[
 A_{N,\Lambda}f(x)=\frac1N\sum_{1\le n\le N}\Lambda(n)f(x-n^2),\quad
 A_{N,\square}f(x)=\frac1N\sum_{1\le n\le N}f(x-n^2),
\]
\[
 A_{N,\PP^2}f(x)=\frac1{\pi(N)}\sum_{p\le N}f(x-p^2).
\]
The first and third operators differ in both weights and normalization. In the divergence theorem the parameter counts the first \(N\) primes instead of bounding their size. These conventions must not be silently identified.

Put \(L(t)=2+|\log t|\), \(L_2(t)=2+\log(2+|\log t|)\), and
\[
 \Phi_c(t)=\exp\!\left(c\frac{L(t)^{1/2}}{L_2(t)}\right)\quad(t>0).
\]
In bilinear forms define \(t^{2/3}\Phi_c(t)\) to be zero at \(t=0\).
For \(t\ge0\), define
\[
 \Psi_C(t)=\int_0^t
 \exp\!\left(C\sqrt{\log(e+u)\log(e+\log(e+u))}\right)\,du.
\]
The square root in this last expression covers the \emph{product} of the logarithms.

\textbf{Theorem 1.1.} For every \(\varepsilon>0\), there is \(C_\varepsilon\) such that the displayed restricted improving inequality holds for every allowed \(N,F,G\) with coefficient \(4\sqrt3/9+\varepsilon\). The \(o(1)\) in the paper is thus a quantifier over \(\varepsilon\), not an unspecified function added to the theorem. Strong improving bounds for \(3/2<p\le2\) are separate corollaries.

\textbf{Theorem 1.3.} Encode the endpoint sparse form and then the stated interior triangle of exponents. Sparsity uses subsets \(E_I\subset I\) of cardinality at least \(|I|/10\), pairwise disjoint over the family. Cardinalities, dilations and

normalizations must be explicit.

\textbf{Theorem 1.5.} Quantify over every nonatomic ergodic measure-preserving system and every infinite set of indices \(S\). The conclusion is existence of an integrable function whose averages along \(N\in S\) fail to converge on a set of positive measure. Do not weaken this to one system or to the full sequence only.

\textbf{Theorem 1.6.} Define \(\mathcal P\) as the primes represented by \(a^2+b^2+1\) with \((a,b)=1\). For every \(A>0\), specify constants \(C_A,X_A\) so that the nonrepresentable \(1\le n<X\), \(n\equiv12\pmod{24}\), have cardinality at most \(C_AX(\log X)^{-A}\) for \(X\ge X_A\).

\textbf{Section 7.} Theorem 7.2 and Corollaries 7.6 and 7.42 are additional targets: the modular estimate, quantitative \(L^p\) growth, and almost-everywhere and \(L^1\) convergence on the stated Orlicz class. They are not substitutes for Theorem 1.5.

\page
\section{The dependency architecture}
\status{Initial map, not a claim that the indicated modules exist already}

\begin{longtable}{p{.15\linewidth}p{.36\linewidth}p{.40\linewidth}}
\toprule
Branch & Principal nodes in the paper & Output and main dependencies\\\midrule
Arithmetic & Section 3, especially 3.1, 3.12, 3.14, 3.20, 3.21, 3.24, 3.27 & Cohen correlations, kernel bounds, Gauss sums and exceptional-conductor bounds.\\
Improving & 4.1, 4.15, 4.19 & Theorem 1.1; uses Section 3 and the decomposition in Section 6.\\
Sparse & 5.1, 5.10, 5.17 & Theorem 1.3; needs the local low estimate and maximal, rather than fixed-scale, high estimate.\\
High--low & 6.5, 6.9, 6.14, 6.16, 6.19, 6.21 & Proposition 4.19; uses primes in progressions with an exceptional term, minor-arc cancellation and multifrequency estimates.\\
Near \(L^1\) & 7.8, 7.15, 7.21, 7.28, 7.2 & Corollaries 7.6 and 7.42; uses quantitative Ionescu--Wainger/sampling inputs and the Section 6 model.\\
Divergence & 8.1, 8.6, 8.8 and the final assembly & Theorem 1.5; uses a character-sum bound, Poisson spacings, fixed-modulus prime equidistribution and the divergence criterion.\\
Goldbach & 9.2--9.10, Section 10, 11.13, 11.19, 9.17, 9.20, 9.22, 9.24 & Theorem 1.6; circle-method mean-square approximation, two-stage sieving, positive main term and exceptional-set assembly.\\\bottomrule
\end{longtable}

The high--low branch is shared by the improving, sparse and near-\(L^1\) results. The divergence branch shares arithmetic foundations but is logically separate from the maximal inequality. The Goldbach branch shares exponential sums and local correlations, but introduces its own mean-square approximation and sieve machinery.

\subsection*{Proposed eventual organization}
Keep declarations under \lean{PrimeSquares}. Suggested future directories are \lean{Arithmetic}, \lean{HighLow}, \lean{Improving}, \lean{Sparse}, \lean{Maximal}, \lean{Ergodic}, \lean{Goldbach} and \lean{External}. Maintain one table linking a manuscript label to each Lean declaration. Use stable LaTeX labels once the sources are available; printed theorem numbers alone will change during proofreading.

For each node record: the exact statement; normalization and parameter ranges; dependencies; an expanded proof; Lean name; external assumptions; build status. The appendix currently gives an inventory, not this complete node-by-node expansion.

\page
\section{A checked finite exceptional-set argument}
\status{Implemented in \lean{PrimeSquares/FiniteAssembly.lean}}

Let \(S\) be a finite set, let \(e_1,e_2:S\to\R\), and let \(t>0\). Define
\[
 B_t=\{n\in S:|e_1(n)|+|e_2(n)|>t\}.
\]
No number-theoretic interpretation is part of these definitions.

\begin{lemma}[Finite energy estimate]
If \(\sum_{n\in S}e_i(n)^2\le B_i\) for \(i=1,2\), then
\[
 |B_t|\le\frac{2(B_1+B_2)}{t^2}.
\]
\end{lemma}
\begin{proof}
For real \(a,b\), the nonnegativity of \((|a|-|b|)^2\) implies \((|a|+|b|)^2\le2(a^2+b^2)\). On \(B_t\), therefore, \(t^2\le2(e_1(n)^2+e_2(n)^2)\). Sum this inequality on \(B_t\), enlarge the nonnegative square sum to \(S\), and divide by \(t^2>0\).
\end{proof}

\begin{lemma}[Positivity outside the exceptional set]
Let \(R(n)\) be a nonnegative integer and suppose that
\[
 R(n)\ge M(n)+e_1(n)-e_2(n)-u(n),\quad
 M(n)\ge4t,\quad u(n)\le t.
\]
If \(n\notin B_t\), then \(R(n)\ge2t>0\).

\end{lemma}
\begin{proof}
Use \(e_1-e_2\ge-|e_1|-|e_2|\) and \(|e_1|+|e_2|\le t\). The lower
bound becomes \(4t-t-t=2t\).
\end{proof}

Combining the two lemmas gives the actual Lean result
\lean{PrimeSquares.zero_count_card_bound}:
\[
 \abs{\{n\in S:R(n)=0\}}\le\frac{2(B_1+B_2)}{t^2}.
\]
The hypotheses about \(M,R,u,e_i\) are part of its statement. In the paper's final
assembly take \(M=\Delta X_n\Theta_n(z)/2\),
\(t=cN(\log N)^{-C_{A_0}}\), and \(e_i=E_i\).
If each mean square is at most \(C_iN^4(\log N)^{-K}\), the bound becomes
\[
 \abs{\{R=0\}}\le
 \frac{2(C_1+C_2)}{c^2}N^2(\log N)^{-K+2C_{A_0}}.
\]
Choosing \(K\) large enough yields the desired logarithmic saving for this finite
range. The analytic estimates, eventual parameter choices, identification of \(R\)
with actual representations, and treatment of the initial short range remain
formalization work. Thus this is the finite last step of the Goldbach proof, not
Theorem 1.6 itself.

\page
\section{Other checked components}
\status{Implemented in \lean{LocalArithmetic.lean} and \lean{SieveConstant.lean}}

\subsection*{Congruences and the shared-prime observation}
For every natural number \(n\) with \(n\equiv1\pmod2\) and \(n\not\equiv0\pmod3\),
the module proves \(n^2\equiv1\pmod{24}\). The proof reduces to the 24 possible
residues; Lean checks the finite case split. For a prime \(p>3\), primality excludes
divisibility by 2 and 3, so the same conclusion follows.

Consequently, if \(r\equiv11\pmod{24}\) and \(p>3\) is prime, then
\(r+p^2\equiv12\pmod{24}\). The restriction \(p>3\) is included explicitly.
The starter also proves the shift equivalences
\[
 m=a^2+b^2+p^2\iff m+1=a^2+b^2+p^2+1,
 \qquad m\equiv11\pmod{24}\iff m+1\equiv12\pmod{24}.
\]
These clarify the relation between the abstract's formulation and Theorem 1.6;
they do not establish an exceptional-set estimate.

Suppose \(p,m\) are prime, \(n=m^2+r\), and \(p\mid n,r\). Then \(p\mid m^2\),
so \(p\mid m\); primality of \(m\) forces \(p=m\). This is the finite divisibility
observation used in Lemma 11.2. The divisor-counting estimate and the full sieve
comparison in that lemma are not yet formalized.

\subsection*{The elementary bracket in Lemma 9.24}
The manuscript reduces its final sieve comparison to
\[
 \Delta\ge\frac{e^{\gamma/2}}{\sqrt\pi}
 \left(\frac{2\sqrt2}{3}\log2-\frac{27}{64}\right).
\]
Lean proves positivity of the parenthesized expression. There is a particularly
short rigorous proof which does not need decimal approximations:
\[
 \sqrt2\ge\frac43,\qquad \log2\ge1-\frac12=\frac12,
\]
where the second inequality is the standard \(1-x^{-1}\le\log x\) for \(x>0\).
Both lower bounds are positive, and therefore
\[
 \frac{2\sqrt2}{3}\log2-\frac{27}{64}
 \ge\frac49-\frac{27}{64}=\frac{13}{576}>0.
\]
The declaration \lean{sieve_bracket_positive} proves this conclusion. The separate
declaration \lean{scaled_sieve_bracket_positive} allows multiplication by any
strictly positive real factor.

This does \emph{not} verify the integral evaluation for \(f_{1/2}(9/8)\), the upper
bound on \(\mathcal W(9/8)\), the factor \(e^{\gamma/2}/\sqrt\pi\), or the stronger
numerical inequality \(\Delta>0.17\). Those must be added before claiming Lemma 9.24.

\page
\section{Improving estimates: the scalar optimization and its inputs}
\status{Unfinished target; the following is the blueprint for Section 4}

Separate the prime parameter from the spatial scale. For prime squares, a sum up
to \(N\) has support at scale \(N^2\); the abstract theorem uses a spatial-scale
variable. A typed name such as \lean{primeScale} versus \lean{spaceScale} prevents
an incorrect substitution of \(N\) for \(N^2\).

Theorem 4.1 first supplies a comparison operator \(B_N\). Applied to indicators,
its decomposition gives, with \(\delta=|F||G|/N^2\),
\[
 N^{-1}|\langle B_N\one_F,\one_G\rangle|
 \lesssim\delta J^s(\log J)^\gamma+
 \delta^{1/2}J^{-r}(\log J)^\beta.
\]

The optimal J, up to bounded factors, is
$$
 J=\delta^{-1/(2(s+r))}(\operatorname{Log}\delta)^{(\beta-\gamma)/(s+r)}.
$$
Prove first the estimate when this J is in the permitted range. If it is too large, use the elementary local kernel estimate. This second branch is essential: choosing an inadmissible J is not an application of the decomposition.

For the prime operator the corresponding bound is
$$
 \delta Q^s(\log Q)^\alpha+
 \delta^{1/2}Q^{-r}
 \exp\!\left(c_1\frac{(\log Q)^\kappa}{\log\log Q}\right)
 +\text{error}.
$$
When $\operatorname{Log}\delta$ is small enough relative to $((\log N)^c$, take the dyadic Q specified by (4.14). Prove separately that it is admissible, that rounding changes the estimate by a bounded factor, and that the error is absorbed. In the complementary range, transfer the comparison estimate using the pointwise domination by B_N. This yields
$$
 \delta^{1-s/(2(s+r))}\Phi_{c_*,\kappa}(\delta),\qquad
 c_* = \frac{c_1s}{2^\kappa(s+r)^{\kappa+1}}+o(1).
$$
For $s=1,r=1/2,\kappa=1/2,c_1=2+\varepsilon$, the critical power is $2/3$ and the limiting coefficient is $4\sqrt3/9$.

\textbf{Separate Lean tasks.} Establish the finite bilinear norm inequalities; formalize the elementary optimization including the two parameter ranges; prove the dyadic-to-full annular summation; and then prove restricted-to-strong interpolation for $p>3/2$. None follows just from writing the numerical value of the coefficient into a declaration.

\page
\section{Sparse bounds: local control and recursion}
\status{Unfinished target; Sections 5 and the stopping-time conventions in Section 2}

The sparse proof needs more than Theorem 1.1. A stopping time $\tau(x)$ depends on the spatial point. Its high term must be controlled by a maximal ℓ^2 estimate over all permitted scales. The low estimate must be local enough that admissibility replaces its local density by the parent density.

The key tasks are these.
\begin{enumerate}
\item Define integer intervals, their dilations, a dyadic grid, and the admissible stopping times. Record the exact support radius of each kernel.
\item Prove Lemma 5.1 from the local kernel estimate, the local low estimate, the maximal high estimate and the square-summable errors. Include the small-scale branch, where the abstract high--low split is not available.
\item Prove Lemma 5.10. Select maximal bad dyadic intervals by the two density tests. Bound the sum of child lengths by $|I_0|/4$. Construct disjoint major subsets and iterate the local inequality.
\item In Lemma 5.17 split according to $\log\tau\le C_0L^2$ and its complement, where $L=\operatorname{Log}(\delta_0^{-1})$. The first range uses the square averages; the second uses the prime-square decomposition with an admissible denominator cutoff.
\item Convert the local sparse form with cI on the input side into the stated form. Prove the required grid/dilation reduction rather than identifying the two families by notation.
\end{enumerate}

For finite input sets, begin with a finite set of scales and a finite recursion. If using an infinite family later, specify its sum and prove the limiting step. This keeps the initial recursive construction elementary and exposes precisely which part needs an infinite argument.

There is a useful formalization trap here. An arbitrary real-valued supremum in Lean uses conditional completeness. Without a boundedness hypothesis, it must not be treated as a maximum with all the usual inequalities. One can first work with finite truncated maxima, or use extended nonnegative reals for a maximal function and prove finiteness afterward.

Finally, the strong sparse estimates for exponents in the interior of the triangle need their own interpolation/convexity argument. They should be separate declarations depending on the endpoint local bound and the trivial bounds, not an additional assumed theorem.

\page
\section{The high--low model and exceptional conductors}
\status{Unfinished target; the main shared arithmetic and analytic branch}

At prime scale N, the annular multiplier is approximated by the model V_N in (6.8). Its ordinary coefficients are normalized unit quadratic Gauss sums. If an exceptional character is present, its contribution has the minus sign displayed in that formula, an induced character modulo each multiple of its conductor, and a continuous model with parameter β.

Use explicit scale-indexed data. For example, define an optional datum at N containing (q_χ,χ,β), and define
$\mathcal M(\chi)$ to be the scales where that character is selected. Do not pick one character and use it at all scales. Page uniqueness must be strong

enough to justify the later regrouping by conductor.

\textbf{Arithmetic layer.} Prove the Cohen correlation by CRT, the odd prime-power evaluation and the explicit 2-adic cases. Build the restricted correlations and Euler products of Section 3 from these identities. Prove the ordinary Gauss bound with its subexponential factor, the real-character bound, and the stronger \(\sigma_\chi B_\chi^{1/2}\ll q_\chi^{-1/25}\) estimate. The last estimate is used to sum over changing exceptional characters.

\textbf{Approximation layer.} Encode Lemma 6.5 and then Lemma 6.9. The primes-in-progressions input must supply a single exceptional datum valid over the interval of partial summation \([N/2,N]\), with uniform errors. A fixed-modulus PNT alone does not provide this growing-modulus input.

\textbf{Exact decomposition.} The ordinary split is by \(q\le Q\). The exceptional split is by \(d=q/q_\chi\le Q/B_\chi\), with its own cutoff. Prove the multiplier identity (6.13) before norm estimates. Empty exceptional sums, including \(Q/B_\chi<1\), must be covered by the definitions.

\textbf{Low and high bounds.} Proposition 6.14 uses inverse transforms and the arithmetic kernel identities. Proposition 6.21 needs Lemma 6.16, the denominator-prefix extension 6.19, the cutoff-difference square functions, and a final sum over \(\chi\). At each scale there is at most one exceptional datum; the square sum over characters and Page uniqueness per dyadic conductor range are separate steps. Only after both bounds and the error estimate are checked does one obtain Proposition 4.19.

\page
\section{The Orlicz maximal estimate and convergence}
\status{Unfinished target; Section 7}

The quantitative Ionescu--Wainger input must retain its constants. Proposition 7.8 specifies a rational-frequency set containing every denominator at most \(Q\), a period \(P\), a denominator bound \(B\), a sufficiently small width, and norm comparisons for a range of exponents. It invokes Tao's Lemma 5.1, Theorems 1.6 and 1.7, and Proposition 1.5. These should have explicit external interfaces if they are not formalized here.

Next prove the continuous multiplier bounds uniformly in \(0<\beta\le1\) (Lemma 7.15), followed by the finite-group measure and sampling argument (Proposition 7.21). The measure is allowed to be complex but has total variation at most one. Dependence of constants on the period or on \(\beta\) would break the later optimization.

Proposition 7.28 combines this low model with an \(\ell^2\) high estimate. The exceptional characters of conductor above \(Q\) vary with scale and are retained in the high term. The low exceptional character, when it exists, is controlled using Page uniqueness. This assembly must use the same model and normalization as Section 6.

For the modular extension, do not stop at the restricted estimate on \(\one_F\). Let \(C_\infty\) bound the masses of the positive kernels. Remove \(|f|\le\lambda/(2C_\infty)\). Decompose the remaining function into level sets
\[
 E_j=\{2^j\lambda/(2C_\infty)<|f|\le2^{j+1}\lambda/(2C_\infty)\}.
\]
Allocate thresholds using a positive summable sequence such as \(a_j=6/(\pi^2(j+1)^2)\). Prove the union inclusion, apply the restricted estimate to each \(E_j\), and prove that the polynomial factor in \(j\) inside the threshold can be absorbed by enlarging the coefficient of \(\Psi_C\). This is a quantitative estimate for this particular Young function, not just sublinearity. It gives the truncated modular estimate (7.3), then (7.4).

Corollary 7.6 follows by layer cake and a one-variable integral estimate, with \(\varepsilon=p-1\). Corollary 7.42 first transfers finite truncated discrete estimates to an invertible probability-preserving system. Prove bounded-function convergence using the cited polynomial-prime result and control the higher prime powers there. Abel summation handles the unweighted prime averages. Finally use Orlicz truncation, doubling and the modular maximal estimate to pass to unbounded functions; use uniform \(L^1\) bounds for \(L^1\) convergence.

\page
\section{Persistent universal divergence}
\status{Unfinished target; Section 8}

For each modulus \(q\), define
\(\Lambda_q=\{b^2\bmod q:(b,q)=1\}\). The initial finite tasks are CRT compatibility, inclusion in the prime-square residue set, and, for odd squarefree \(q\),
\[
 |\Lambda_q|=\frac{\varphi(q)}{2^{\omega(q)}},\qquad
 s_q=\frac q{|\Lambda_q|}=\prod_{p\mid q}\frac{2p}{p-1}.
\]
The inclusion uses Dirichlet's theorem for a unit square root; it must not claim that every prime residue, including nonunits, is part of \(\Lambda_q\).

Lemma 8.8 expands each quadratic-residue indicator as \(\tfrac12(1+\chi_p-\one_{\{0\}})\). Terms containing a zero indicator are bounded by a constant depending on the number of shifts. For the others, apply the Weil bound to the squarefree product of the distinct shifted linear factors. This proves the correlation hypothesis for the imported Poisson-spacings theorem.

Choose pairwise disjoint blocks of odd primes with block sizes tending to
infinity, and a disjoint prime sequence \(u_j\). The block products \(q_j\)
satisfy \(\PP_{q_j}(\Lambda_{q_j})\le2^{-j}\), whereas
\(\PP_{u_j}(\Lambda_{u_j})\ge1/3\). The construction must ensure the combined
collection is pairwise coprime.

Theorem 8.6 supplies Poisson spacings. The thickening identity in the proof
expresses the covered proportion as
\[
 \PP_{q_j}(\Lambda_{q_j}^{\gamma})
 =\int_0^\gamma F_j(\theta)\,d\theta+O(s_{q_j}^{-1}).
\]
Dominated convergence gives \(1-e^{-\gamma}\), so the deficit is \(o(\gamma)\).
The pair-separation condition uses LaVictoire's Lemma 3.2 in addition to this
one-gap distribution; it is not an automatic restatement of Poisson convergence.

Finally, fixed-modulus prime equidistribution gives limiting mass
\(1/|\Lambda_Q|\) at every \(a\in\Lambda_Q\). The strict lower bound required
by (8.5) then holds with, for example, \(\beta=1/2\). Apply the full imported
divergence criterion, including its transference/Banach-principle conclusions,
to obtain exactly the persistence and system quantifiers of Theorem 1.5.

If the chosen formal ergodic infrastructure assumes invertibility, a separate
extension/transfer argument is needed to match the unqualified system statement
in Theorem 1.5. Simply adding invertibility would narrow the theorem.

\page
\section{The Goldbach branch}
\status{Only the finite final assembly and small supporting pieces are checked}

The reductions in Section 9 produce a lower sieve count minus an upper correction
count. Their errors must have mean-square bounds with an arbitrarily large
logarithmic saving. The common main term is
\(X_n\Theta_n(z)\); its positivity and uniform lower bound are separate lemmas.

\textbf{Circle method.} Lemma 9.10 is the principal target. Its coefficients are
independent of \(n\), and its conclusion is a mean square of a sum over auxiliary
moduli and \(\ell\). Section 10 supplies the minor-arc bound, the major-arc local
factor \(G_R\), the truncated continuous factor \(H_{\ell,R}\), the tail estimate
and the major-arc error. The same small-prime parameter \(R\) must be retained
in both main-term factors until its tails have been shown to be summable.

\textbf{Sieve.} Lemma 11.2 replaces variable sets of sieve primes by fixed sets,
which is needed before applying Lemma 9.10 to coefficients independent of \(n\).
The exact local densities are computed in Lemmas 11.6 and 11.8. For primes at
most \(R\), the uniform product dimensions are \(2/3\) and \(3/2\); one cannot
apply the desired half-dimensional and linear sieves over the whole range.

Lemma 11.13 removes \(p\le R\) first at level
\(D_0=\exp((\log\log N)^3)\). The remaining level is \(D/D_0\).
Because outer weights have both signs, the choice of preliminary upper or lower
weights must depend on that sign. Prove this finite algebra before estimating
the two stages. The coefficient bounds and independence of \(n\) must survive
the combination. The outer dimensions are then \(1/2\) and \(1\).

Lemma 11.19 performs the weighted sum over \(\ell\). It needs the cited mean-value
theorem for multiplicative functions and the relevant short-interval uniformity.
Track the cancellation of the factors at \(p\le R\) and the replacement of
\(H_{\ell,R}\) by \(H_\ell\); neither can be dropped at the definition stage.

The outputs are Propositions 9.17 and 9.20. Lemma 9.22 bounds the common main
term below. Lemma 9.24 compares the sieve constants. Their combination gives
(9.25), and the checked finite result in Section 4 then applies. The remaining
asymptotic task is to choose the constants in the correct order, show the
\(O(N^{\varepsilon})\) nuisance is smaller than the positive main term, discard
the initial range, and pass from scale \(N^2\) to general \(X\).

\page
\section{Proposed external-input register}
\status{Candidate interfaces; not declarations already installed in the starter}

The user's permission to leave deep theorems unformalized makes a conditional
development appropriate. The exact declarations should be approved mathematically
by comparison with their sources. The list below is an initial register, not a
claim that each result is absent from current Mathlib.

\small
\begin{longtable}{p{.11\linewidth}p{.39\linewidth}p{.41\linewidth}}
\toprule
ID & Published input & Required interface and use\\\midrule
NT01 & PNT in progressions with exceptional term and Landau--Page; paper (2.5)--(2.6), reference [22] &
Uniform growing-modulus error, one datum on an annulus, induced characters, and
uniqueness strong enough across scales. Used in Section 6.\\
NT02 & Siegel--Walfisz and fixed-modulus equidistribution &
Full quantifier order for modulus, residue, exponent and threshold. Used where
polylogarithmic moduli or fixed progressions suffice; not a replacement for NT01.\\
NT03 & Ren [40, Theorem 1] &
Quadratic prime exponential-sum cancellation with exactly the denominator and
arc-width ranges needed in (6.7) and (10.1).\\
NT04 & Bombieri--Vinogradov, Brun--Titchmarsh, Mertens-type estimates; Section 2.6 &

Maxima over residues and endpoints, divisor weights, and constants uniform in
the auxiliary moduli. Used in Section 10 and the sieve.\\
NT05 & Classical quadratic Gauss evaluations and Weil character-sum bounds &
Primitive and induced character conventions; primes and prime powers, including
2; squarefree-polynomial hypothesis for Lemma 8.8.\\
HA01 & Separated-frequency maximal inequality [25, Theorem 1.1] &
Precise separation and cardinality dependence. Prove its adaptation, transference
and uniformity in \(\beta\) in Lemma 6.16.\\
HA02 & Tao [45], Lemma 5.1, Theorems 1.6--1.7 and Proposition 1.5 &
Quantitative major-arc construction, multiplier theorem and sampling comparisons.
Keep \(r,k,B,P,\varepsilon,p\) and vector-valued constants explicit.\\
HA03 & Hardy--Littlewood, Calder\'on--Zygmund, Khintchine and Rademacher--Menshov &
Only use an external declaration where the pinned library does not already
provide the needed statement. Preserve the \(p\downarrow1\) dependence.\\
\bottomrule
\end{longtable}
\normalsize

Do not collapse these into a single assumption saying that all estimates needed
in the paper hold. An import should be independently recognizable as a published
theorem and should not assume the novel conclusion to be checked.

\page
\subsection*{External inputs continued}
\small
\begin{longtable}{p{.11\linewidth}p{.39\linewidth}p{.41\linewidth}}
\toprule
ID & Published input & Required interface and use\\\midrule
ER01 & LaVictoire [27, Theorem 3.1 and Lemma 3.2], with the principles used in the paper's Theorem 8.1 &
CRT families, two coprime sequences, thickening deficit, pair separation and
residue-frequency hypotheses; full persistent universal divergence conclusion.\\
ER02 & Granville--Kurlberg [14, Theorem 1], in the specialization 8.6 &
Uniform correlations for distinct shifts and the hypotheses on local densities;
convergence of normalized cyclic gaps.\\
ER03 & Polynomial-prime pointwise convergence [35, Corollary 2(ii)] &
The bounded-function dense class used in Corollary 7.42, with the correct weights
and systems. Prime powers and Abel summation remain internal tasks.\\
SV01 & Rosser--Iwaniec coefficient-form sieve and fundamental lemma [21] &
Weights, support, signs, coefficient bounds, product hypotheses, sieve functions
and quantitative remainder; prove the two-stage composition in Lemma 11.13.\\
SV02 & Granville--Koukoulopoulos [13] and Shiu [41] &
Mean values of the particular multiplicative weight and uniform estimates in the
retained ranges used by Lemma 11.19.\\\bottomrule
\end{longtable}
\normalsize

\subsection*{Represent imports as hypotheses first}
For a new branch it is often helpful to package the external inputs as a named
structure and prove a theorem with that structure as an explicit argument.
This makes the logical boundary visible without immediately adding global
axioms. Once the interfaces have been audited, a separate file can instantiate
the structure from selected quoted theorems.

In either design, dependency output for a headline theorem must agree with the
published import register. A proof conditional on an estimate proved nowhere in
the project or cited literature should be labeled incomplete, even if Lean
accepts it with that estimate as a hypothesis.

\subsection*{Possible reuse from the Hua project}
The Hua repository contains finite cyclic Fourier infrastructure, quadratic local
arithmetic and analytic assembly. Some may be reusable after comparing
definitions. Its prime-square weights are those of its own \(W\)-trick argument,
not automatically the operators \(A_{N,\Lambda}\) in this paper. Reuse requires
checking signs, normalizations, finite versus infinite groups, and transitive
axiom dependencies. No reuse has been counted as completed work here.

\page
\section{Points to settle during manuscript proofreading}
These are formalization requirements or visible editorial issues, not a verdict
that the main mathematical arguments are wrong.

\begin{enumerate}
\item \textbf{Freeze the version.} The attached paper has 96 pages and Section 7.
Its current numbering is the one used in this document. Match the final LaTeX
labels rather than importing numbering from older discussions.
\item \textbf{Repair the Section 7 references.} The opening of Section 7 and the
last sentence before the proof of Corollary 7.6 refer to Theorem 1.5. In this
snapshot Theorem 1.5 is the divergence theorem, so these references cannot name
the maximal-inequality consequence intended there.
\item \textbf{Preserve the two endpoint functions.} The improving loss is
\(\exp(c\sqrt{L}/L_2)\); the modular function uses
\(\exp(C\sqrt{\log(e+t)\log(e+\log(e+t))})\). These are different scales.
\item \textbf{Separate bounded and unbounded input.} A negligible prime-power
contribution for bounded functions is sufficient for the dense-class convergence
step; it is not itself a uniform error bound for every \(L^1\) function.
\item \textbf{Make exceptional data consistent.} Record the annular data used in
partial summation and prove the regrouping over \(\mathcal M(\chi)\). Do not
replace this by a single exceptional character fixed for all \(N\).
\item \textbf{Expose uniformity in the Goldbach range.} All \(o(1)\), tail errors
and positivity bounds must be uniform in admissible \(n,\ell\) and auxiliary
moduli. Write the order of choosing \(A_0,K,C\) and all thresholds explicitly.

```
\item \textbf{Retain fixed sieve-prime sets.} The independence from \(n\) after
Lemma 11.2 is required by the mean-square estimate. The coefficient combination
in the pre-sieve must preserve this independence.
\item \textbf{Check strictness and small cases.} Empty sets, \(q=1\), powers of 2,
\(N\ge2\), \(p=2,3\), and equality at density/threshold boundaries should be
covered by exact definitions, not silently discarded.
\end{enumerate}

The present work has not audited every cited theorem or every proof in the PDF.
In particular, successful checks of the starter do not validate any unfinished
node elsewhere in the map.

\page
\section{What is needed to continue}
The PDFs were enough to start. The next useful input is the final LaTeX project:
all source files, bibliography, custom macros and any code used for numerical
estimates, together with the PDF generated from those files. This makes the
statements and labels unambiguous and lets the map track proofreading changes.

GitHub is useful for versioning and automated builds, but an account is not
required to write or check Lean locally. This archive is a normal Lean project;
it can be uploaded later. The toolchain and lockfile are already selected.
There is no need for the author to learn Lean before mathematical work can begin.

The next mathematical milestone should be one coherent branch. A practical
sequence is:
\begin{enumerate}
\item Encode the final target statements and audit their quantifiers against the
LaTeX. Build a stable statement map.
\item Complete a substantial finite arithmetic module, such as the quadratic
Cohen identity with all prime-power cases, or complete the scalar optimization
in Theorem 4.1.
\item Specify and audit the deep-input interfaces. Prove one full branch from
those interfaces, without assuming its novel intermediate estimates.
\item Add the remaining branches and report the exact dependencies of each
headline theorem separately.
\end{enumerate}

For the Goldbach branch, the existing checked finite assembly supplies an endpoint
to which the circle-method and sieve components can connect. For the harmonic-
analysis branch, the shared high--low decomposition is the principal reusable
milestone. The divergence branch can be developed separately once its external
criterion and Poisson-spacings interfaces are audited.

\textbf{Completion criterion.} A full conditional formalization requires a fresh
build of every target theorem, a transitive axiom audit with no unfinished proof
axiom, and a human comparison of the final statements and imported inputs with
the manuscript and sources. A long blueprint, a clean source scan, or a passing
build of the present starter alone does not meet that criterion.

\textbf{Current deliverable.} This is an initial, reproducible starting point with
small checked components and an explicit account of the much larger unfinished
work. It should not yet be described in an arXiv or journal submission as a
formalization of the paper.

\page
\appendix
\section{Inventory of numbered statements}
The following inventory was extracted from headings in the attached PDF. Planned
names are suggestions only. A status of ``target'' means no proof of that numbered
statement is present in the starter. Checked supporting subclaims are described
separately in Sections 4--5; they do not change the status of the enclosing paper
theorem or lemma.

t:improvingfixed,theorem,1.1,3,1,Introduction,212,"conditional: Both conclusions for the genuine full von-Mangoldt square average, every positive integer N, the exact source interval and its cardinality, all finite F,G subsets, every coefficient cstar>4 sqrt(3)/9, and every real 3/2<p<=2. The strong result proves actual output lp membership and the literal normalized sum form, for all lp inputs, hence also the supported inputs in the source. The implication is complete under the explicit independent deep inputs. PNT limits, compatible progression/Ren/Ghosh data existence, and the independent ordinary-square global decomposition remain unformalized hypotheses. Its analytic globalization remains external; the plus/minus spatial reflection is proved with the same constants at checkpoint783. Theorem1.1 and Propositions4.19/6.21 are complete conditional implications under their separate inputs; the current corrected numbered paper targets are all matched, with independent inputs and stronger unnumbered alternative-route assertions retaining their documented scopes.","Let \(I=[-N^2,2N^2]\cap\mathbb Z\). For all \(F,G\subseteq I\), \begin{align} \frac1{|I|} \bigl|\langle A_{N,\Lambda}\mathbf1_F,\mathbf1_G\rangle\bigr| &\ll \left(\frac{|F|}{|I|}\frac{|G|}{|I|}\right)^{2/3} \Phi_{4\sqrt3/9+o(1)} \left(\frac{|F|}{|I|}\frac{|G|}{|I|}\right). \end{align} Consequently, "
t:sparsebound,theorem,1.3,3,1,Introduction,287,"conditional: Both displayed conclusions are complete conditional implications: the literal full maximal indicator for every integer N>=2, arbitrary finite F,G including empty sets, actual finite interval collections with actual pairwise disjoint major subsets of size at least one tenth, the exact endpoint density exponent and paper Phi for every cstar>4sqrt(3)/9, and every point of the full open triangle in exact reciprocal/barycentric coordinates. Constants precede F,G. All stopping, packing, support, local endpoint, interpolation and sparse deductions are proved. No paper-specific deduction in either conclusion remains. The recorded prime limits, compatible raw Page/distribution data, Page uniqueness, general smooth multifrequency/sampling, independent ordinary-square stopping interface and complementary-exponent prime maximal input remain unproved explicit hypotheses, including their stated compatibility boundaries. The general auxiliary Section5 statements are separately partial. The proposed dyadic qualification of l:sparserecursion is unapplied; the actual prime-square all-cutoff reduction is proved.","Let \(F,G\subset\mathbb Z\) be finite. There is a sparse collection of intervals \(\mathcal S\) such that \begin{align} \bigl|\langle A_\Lambda^*\mathbf1_F,\mathbf1_G\rangle\bigr| &\ll \sum_{I\in\mathcal S}|I| \left(\frac{|F\cap I||G\cap I|}{|I|^2}\right)^{2/3} \Phi_{4\sqrt3/9+o(1)} \left(\frac{|F\c"
t:pet,theorem,1.5,4,1,Introduction,376,"conditional: Both parts are complete conditional implications. Part(i): the actual enumerated prime squares are persistently universally L1-bad on every truly nonatomic ergodic measure-preserving probability system, with every infinite cutoff set and an actual measurable positive-measure divergence set. CRT, Dirichlet representation, correlation counts, large-prime block construction, all moment/thickening/difference limits, uniform square-root fibers and the fixed-progression PNT pushforward are proved. The original badness theorem, Sawyer, Conze, general Weil and fixed-progression PNT remain separate unproved general inputs. Granville–Kurlberg is not used by part(i). A checked moment proof replaces the source strict finite-fraction argument, which has an exact kernel counterexample. Part(ii) is a complete conditional implication: an absolute positive constant before every invertible measure-preserving probability system, every 1 < p <= 2 and every Lp input; the proper actual maximum over the first m prime squares for all m >= 1 is finite almost everywhere, belongs to Lp and has the exact displayed exponential norm bound. The prime-counting/enumeration normalization, finite sums, first-prime case and equality of both full maxima are proved with no PNT or enumeration input. The proof uses the already proved Corollary7.6 and the precise independent general strong Calderon input, plus the earlier Theorem7.2 independent inputs. It does not use the bounded-class convergence input. At checkpoint1264 the current public export consumes the proved finite signed maximal theorem at constant6; a supplied RawFiniteSignedMaximalInput and its constant R are no longer hypotheses. No remaining source clause within the agreed conditional scope. General inputs and their exact convention bridges remain unproved. The user confirmed the three Section8 edits; the selected project manuscript now contains the agreed moment proof.","Let \(p_k\) denote the \(k\)-th prime, and put \(n_k=p_k^2\). \begin{enumerate}[label=\textup{(\roman*)}] \item The sequence \((n_k)\) is persistently universally \(L^1\)-bad. More precisely, for every nonatomic ergodic measure-preserving probability system \((X,\mu,T)\) and every infinite set \(\ma"
t:repmotthm,theorem,1.6,5,1,Introduction,453,"conditional: The full quantitative exceptional-set theorem is complete: for every A>0, the actual exceptional set of positive n<X congruent12 mod24 without a prime plus a square-of-prime representation whose first prime is a primitive sum of two squares plus1 has size O_A(X(log X)^(-A)), eventually at every real X. The representation and exceptional-set membership are exact. The common-cutoff Section11 estimates, positive numerical gap, arbitrary logarithmic mean-square saving, all arithmetic losses, small n and the passage from N^2 to real X are discharged. Explicit independent general SW, BV, Ren/Ghosh, one-stage sieve, effective multiplicative mean, Mertens, normalized sieve values/continuity and primitive two-square criterion remain unproved theorem parameters. No own-paper endpoint is a hypothesis. At1259: Section11 and the final quantitative Goldbach theorem are complete in the agreed conditional scope, using the supplied corrected presieving statement. Every paper endpoint is discharged; only explicit independent general classical inputs and their normalizations remain unproved. Original manuscripts are unchanged and the supplied Section11 replacements still require user application. No additional completion credit is claimed for stronger unnumbered assertions in alternate proof routes. At1261: Proved the full PrimitiveTwoSquaresCriterion from pinned Mathlib and elementary algebra, and proved W(alpha) convergence/nonnegativity for every alpha>1. Constructed a concrete nonzero compactly supported smooth seed. The next stage exports the Section9 arithmetic and headline statements without the former criterion or seed hypotheses, then reconciles the stale Section9 map. User manuscript edits remain in progress. At1262 the final endpoint is exported from GoldbachSection11Inputs alone: the primitive two-square criterion is proved internally and a fixed nonzero smooth compact seed is constructed. The real-X bound and zero exceptional density need no separate arithmetic or seed assumption. At1262: Every Section9 numbered source claim and its final quantitative theorem is complete in the agreed scope. All elementary arithmetic reductions are now proved without an extra primitive two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is constructed. Only the explicit independent analytic inputs remain for the circle-method/sieve/headline estimates. The user is applying previous manuscript edits; no application is assumed and original sources are unchanged.","[Quantitative exceptional set] Almost all integers congruent to 12 modulo 24 can be written as \[a^2+b^2+p^2+1, \qquad a^2+b^2+1\in\mathcal P,\quad p\in\mathbb P. \] More precisely, if \[E_2(X)=\{1\leq n<X:n\equiv12\pmod{24},\ n\notin\mathcal P+\mathbb P^2\}, \] then, for every $A>0$, \[|E_2("
d:sparse,definition,2.9,14,2,Notation and preliminaries,1235,"formalized: General interval collections

with actual disjoint finite major subsets; eta=1/4 gives the preliminary definition, and eta=1/10 gives the introductory theorem convention. The finite-family specialization is proved equivalent.","A collection $\mathcal S$ of intervals is sparse if, for every $I\in\mathcal S$, there is $E_I\subset I$ such that $|E_I|\geq|I|/4$ and the sets E_I, $I\in\mathcal S$, are pairwise disjoint."
d:admiss,definition,2.10,14,2,Notation and preliminaries,1251,"formalized: The literal standalone linear-scale admissible dyadic stopping-map predicate is exported on actual finite indicator inputs. Lean proves equality with the displayed all-real-radius finite-count inequality and all convergence/boundedness prerequisites. The earlier actual prime-square spatial N² admissibility is also proved. The accepted fixed-radius and two-direction comparison remarks are also proved, including the exact factor two. The current full upload explicitly separates the fixed radius and the sufficiently large admissibility coefficient, matching the checked generic sparse theorem.","Let $f=\mathbf1_F$ be supported in $3I_0$. A map $\tau:I_0\longrightarrow\{2^j:1\leq2^j\leq|I_0|\}$ is admissible if, for every $x\in I_0$, \begin{align} \sup_{M\geq\tau(x)}\frac1M \sum_{|y-x|\leq CM}f(y) \leq C_{\rm adm}\frac{|F|}{|I_0|}. \end{align} where $C>1$ is a fixed radius constant and $C_{\"

t:improvinggeneral,theorem,4.1,25,4,Proof of the improving inequalities,2330,proved: Complete abstract implication from the hypotheses printed in the source. Verifying those hypotheses for prime squares is a separate obligation.,"Let A_N and B_N be positive convolution operators whose kernels are supported in an interval of length $O(N)$. Suppose that \begin{align} |A_Nf(x)|&\leq(\log N)^aB_N|f|(x),\\ |B_Nf(x)|&\ll N^{-v}\|f\mathbf1_{[x-CN,x+CN]}\|_1, \qquad 0\leq v<1, \end{align} and that $s\geq1-v$, $r>0$, and, wheneve"
c:improvinggeneral,corollary,4.15,27,4,Proof of the improving inequalities,2463,"proved: Complete strong lp-to-lp statement, including p=2 and the source operator hypotheses.","Assume in addition that A_N and B_N are uniformly bounded on ℓ^2. If \begin{align*} \frac{2(r+s)}{2r+s}<p\leq2, \end{align*} then, for $f\in \ell^p(\mathbb{Z})$, \begin{align} \|B_Nf\|_{p'}+\|A_Nf\|_{p'} \ll_p N^{1/p'-1/p}\|f\|_p. \end{align}"
p:decompositionofan,proposition,4.19,28,4,Proof of the improving inequalities,2541,"conditional: All displayed clauses for the actual common selected source low/high/error family: exact all-input annular decomposition, actual l1-to-l-infinity low norm, local bound for all l1 inputs with the supremum over every real M>=N, sharp fixed dyadic and actual countable maximal high bounds for every real Q>=2, every allowed starting threshold, every error exponent A>0, bounded Q and the exact printed high-symbol identity. One cutoff coefficient is chosen before epsilon and A; the operator family never changes with these parameters. The implication is complete under PrimeAsymptoticInputs, PagePrimeSquareDistributionInputs c, RawPageUniquenessInput c and SmoothCircleBourgainInput C. Their independent analytic truths and compatible raw-data existence remain external. No own-paper decomposition, low bound, approximation error or maximal conclusion is an input. The current corrected numbered paper targets are all matched; independent inputs and stronger unnumbered alternative-route assertions retain their documented scopes.","Let \(N\) be dyadic, let \(Q\geq2\), and suppose that \["

\log Q\leq c_0(\log N)^{1/2}, \] where \(c_0>0\) is a sufficiently small absolute constant. Then \begin{align} \widetilde A_{N,\Lambda} = \operatorname{Low}_{Q,N} +\operatorname{High}_{Q,N}+E_{Q,N}, \end{align} where \begin{align} \|\operatorn"

l:localsparse,lemma,5.1,30,5,Proof of the sparse bounds,2721,"proved: Complete abstract implication with the exact source exponents, all 0<=v<1, s>=1-v, r>0, gamma>=beta>=0 and A>1/2, arbitrary physical dyadic stopping times, actual localized low/high/error outputs, all-real-radius admissibility, arbitrary fixed positive radii, parent-length normalization, empty sets and the full bounded density range. The error symbol may be an arbitrary almost-everywhere bounded function; its operator norm follows from the proved Fourier isometry. The normal decomposition and norm estimates are the printed hypotheses, not extra deep inputs.","Fix constants \(C\geq1\) and \(c>2C+1\). Let \((B_M)\) be a family of positive convolution operators satisfying \begin{align} |B_M f(x)| \ll M^{-v}\|f\mathbf1_{[x-CM,x+CM]}\|_1, \qquad 0\leq v<1. \end{align} Let \(s\geq1-v\), \(r>0\), and \(\gamma\geq\beta\geq0\), and suppose that, whenever \(M\) is"

l:sparserecursion,lemma,5.10,31,5,Proof of the sparse bounds,2905,"proved: The actual prime-square finite stopping construction, disjoint components, real-radius admissibility, exact kernel localization, terminating cost recursion and actual sparse major subsets are proved, with a proved all-cutoff reduction for the original averages. A general finite recursive-cost implication is also proved. The complete general dyadic implication is now proved for arbitrary positive compact-support kernels, every fixed odd support dilation, arbitrary Psi, the full untruncated maximum and genuine quarter-sparse major sets. The uniform bound and finite approximation of the full maximum are deduced from the local hypothesis. The local hypothesis is imposed only on maps admissible on the whole interval; an extension argument proves the needed restricted version. No own-paper deduction remains under the accepted dyadic and independent-admissibility-constant conventions. The proof constructs actual sparse sets and the full maximum from the stated local hypothesis; no additional analytic estimate is assumed.","Suppose that every admissible τ satisfies \begin{align} |\langle T_\tau\mathbf1_F,\mathbf1_G\rangle| \ll |I_0|\,\Psi\left(\frac{|F|}{|I_0|}, \frac{|G|}{|I_0|}\right) \end{align} for $F\subset cI_0$ and $G\subset I_0$, where $(T_N)_{N\in2^{\mathbb N}}$ is a family of positive convolution operato"

l:primeendpointlocal,lemma,5.17,33,5,Proof of the sparse bounds,3047,"conditional: Complete source implication for the actual annular von Mangoldt square average: every fixed real support dilation >=1, every positive spatial radius, every fixed admissibility constant, physical dyadic stopping values including scale1, literal all-real-radius quadratic averages, empty sets and the exact parent-length normalization. The bound holds for every cstar>4sqrt(3)/9. Proposition4.19 is derived from the already-listed independent inputs in the terminal theorem, rather than assumed as an extra own-paper input.","Let $f=\mathbf1_F$ and $g=\mathbf1_G$, where $F\subset cI_0$ and $G\subset I_0$, and put $\delta_0=\frac{|F||G|}{|I_0|^2}.$ Let $\tau:I_0\to\{2^k:(2^k)^2\leq|I_0|\}$ be admissible at the spatial scale $\tau(x)^2$, in the sense that \begin{align} \sup_{M\geq\tau(x)}M^{-2} \sum_{|y-x|\leq CM^2}f(y) \l"

l:prime-square-input,lemma,6.5,36,6,The high--low estimates,3322,"conditional: Complete corrected source lemma, with one genuine optional Page datum per N selected before Q, all q<=R^(11/10), the exact induced character/selector/exceptional model and inverse-fifth major error, and the full complementary R^(-1/4)*(log N)^d minor bound. The source Q-range, uniform sufficiently-large-N threshold, R^4<=N/2 and log N>=1 are proved. The general fixed-level uniform Page-prefix theorem and raw Ren/Ghosh estimates remain explicit independent unproved hypotheses.","If \((a,q)=1\), \(q\leq R^{11/10}\), and \(|\theta|\leq R/(qN^2)\), then \begin{align} \widehat{\widetilde A}_{N,\Lambda}(a/q+\theta) &=\mathfrak s(a,q)\widehat{\widetilde M}_N(\theta) -\mathbf1_{q_0\mid q}\mathfrak s_{\chi_q}(a,q) \widehat{\widetilde M}_{N,\beta}(\theta) +O(R^{-5}). \end{align} Her"

l:aaplemma,lemma,6.9,37,6,The high--low estimates,3466,"conditional: Complete printed approximation lemma for the literal selected source error family, every real Q>=2 and every integer N in the Section6 source range. One positive source cutoff coefficient is chosen before all A>0; the exact Q^(-1/2)*(1+log N)^(-A) operator and all-l2 function bounds are proved. The optional Page data and radius are the same actual selected family as Proposition4.19. The previously explicit compatible raw distribution/Ren/Ghosh data remain unproved general inputs; no new own-paper estimate is assumed. No remaining source clause within the agreed conditional scope.","[Approximation] For every \(A>0\), \begin{align} \|E_{Q,N}f\|_2 \ll_A Q^{-1/2}(1+\log N)^{-A}\|f\|_2. \end{align}"

p:lowcontribution,proposition,6.14,39,6,The high--low estimates,3789,"conditional: Complete printed low proposition for the actual selected source low operator: every real Q>=2, every integer N in the common source range, one absolute positive constant for the literal all-real-radius local bound and the l1-to-linfinity norm bound. The local result holds for every complex l1 input using |f| and hence the stated nonnegative inputs, with fixed spatial constant1. Ordinary and induced exceptional terms use the complete conductor range and exact source cutoffs. Only the previously recorded compatible source-data boundary remains; no new mathematical input is added. No remaining source clause within the agreed conditional scope.","For nonnegative \(f\), \begin{align} |\operatorname{Low}_{Q,N}f(x)| \ll Q\log(2Q) \sup_{M\geq N}M^{-2} \sum_{|y-x|\leq CM^2}f(y). \end{align} Consequently, \[\|\operatorname{Low}_{Q,N}f\|_\infty \ll N^{-2}Q\log(2Q)\|f\|_1. \]"

l:notBourgain,lemma,6.16,41,6,The high--low estimates,4009,"conditional: The full actual annular source maximum with the printed first power of (1+s) is proved under the precise independent rational smooth multifrequency/circle-transference input and the previously recorded general smooth input. Every source dyadic scale N>=2^s, every s>=0, scale1 and the small denominator indices are included. The rational common period, linear cost, weight localization, actual annular square-function error and all earlier scale costs are proved. Beta may vary with the scale, a stronger conclusion than the source fixed-beta statement. No own annular deduction remains. The independent smooth multifrequency theorems and sampling remain explicit unproved inputs. The proof uses the rational-frequency refinement rather than replacing the general squared-log loss by a first power; a matching expository replacement proof is saved separately.","[Multifrequency estimate] Let \(0<\beta\leq1\), and let \(\mathcal R_s\) be any subset of the reduced fractions with denominators \(q\sim2^s\). Then \begin{align} \left\| \sup_{\substack{N\in2^{\mathbb N}\\N\gtrsim2^s}} \left| \left(\sum_{a/q\in\mathcal R_s} c_{a,q}\widehat{\widetilde M}_{N,\beta}("

c:orlicz-prefix,corollary,6.19,42,6,The high--low estimates,4081,"conditional: The full source bound with square (1+s)^2 loss is proved for all s>=0, all source dyadic times including scale1, every real denominator cutoff simultaneously and every integer L2 input. The additional fixed bounded measurable multiplier clause is included, with actual essentially bounded Fourier operators and no continuity restriction. Beta may also vary with the scale. No own corollary deduction remains. The independent rational smooth/circle-transference theorem and the prior general smooth input remain explicit unproved hypotheses; the full additional fixed measurable multiplier clause is proved, not added as an external input.","Let \(0<\beta\leq1\), \(s\geq0\), and \(|c_{a,q}|\leq b\). Then \begin{align} &\left\| \sup_{\substack{N\in2^{\mathbb N}\\N\geq2^s}} \sup_K \left| \left(\sum_{\substack{q\sim2^s\\q\leq K}} \sum_{a\in\mathbb A_q} c_{a,q} \widehat{\widetilde M}_{N,\beta}(\xi-a/q) \eta_s(\xi-a/q)\widehat f(\xi) \right"

p:highupperbound,proposition,6.21,43,6,The high--low estimates,4143,"conditional: Both source clauses are complete checked implications: the actual countable dyadic supremum and every individual output, all real Q>=2 and N0>=2 in the allowed logQ<=c0 sqrt(logN0) range, one positive c0 independent of epsilon,

the exact source radius and complementary narrow-cutoff multiplier, changing genuine exceptional data, and the leading coefficient 2+o(1) in precise epsilon form. A separate uniform estimate covers bounded Q; its harmless regularization agrees with sqrt(logQ)/loglogQ once logQ>=2. No paper-specific deduction in this proposition remains. The two prime asymptotic limits, the general smooth multifrequency/sampling input, raw Landau-Page uniqueness (including the L-function bridge), and the existence/selection of source-compatible exceptional zero data remain explicit external boundaries. The stronger auxiliary statements 6.16 and 6.19 are not awarded completion.","Let $N_0\geq2$ and suppose that $\log Q\leq c_0(\log N_0)^{1/2}.$ Then, for every dyadic $N\geq N_0$, \begin{align} \|\operatorname{High}_{Q,N}f\|_2 &\ll Q^{-1/2} \exp\left((2+o(1))\frac{\sqrt{\log Q}}{\log\log Q} \right)\|f\|_2, \\ \left\| \sup_{\substack{M\geq N_0\\M\in2^{\mathbb N}}} |\operatorn"

t:orlicz-maximal,theorem,7.2,46,7,Quantitative maximal estimates near \(L^1\),4494,"conditional: Complete printed Theorem 7.2 as an implication of explicit independent standard inputs: all three actual families (von Mangoldt squares, ordinary squares, unweighted prime squares), every integer cutoff N >= 2, every complex finitely supported function and positive level, with common absolute C, C0 and K >= 1. All three conclusions are proved, including finite level sets: the truncated modular bound, unrestricted modular bound and restricted bound for every finite F and t >= 1. The final theorem is stated with literal sums over all integers and finite support, using the actual integral gauge. The ordinary branch derives the actual discrete circle-model error, maximal comparison, low/high restricted bound and full-cutoff reconstruction from the independent scalar Weyl input and general IW inputs; no own restricted or high/low conclusion is assumed. The unweighted-prime transfer uses proved Mathlib Chebyshev bounds without a new PNT input. At checkpoint1264 the current public export consumes the proved finite signed maximal theorem at constant6; a supplied RawFiniteSignedMaximalInput and its constant R are no longer hypotheses. No remaining clause of Theorem7.2 or Corollaries7.6/7.46 within the agreed conditional scope. The explicitly recorded independent inputs and their published-theorem bridges remain unformalized. Stronger standalone auxiliary parameter/full-generality ranges and later badness/sieve results remain separately tracked.","[Orlicz maximal estimate] There are absolute constants \(C,C_0\geq1\) such that the following holds. Choose \(A_N\) from \(A_{N,\Lambda}\), \(A_{N,\mathbb N^2}\), and \(A_{N,\mathbb P^2}\), and put \(A^*f=\sup_{N\geq2}|A_Nf|\). Then, for every finitely supported \(f:\mathbb Z\to\mathbb C\) and every"

c:orlicz-p,corollary,7.6,46,7,Quantitative maximal estimates near \(L^1\),4528,"conditional: Complete printed Corollary 7.6 as an implication of the already recorded Theorem 7.2 independent inputs. One absolute D > 0 works for all three actual families, every 1 < p <= 2 and every integer lp input. The literal all-integer-cutoff maximal function is proved to belong to lp with norm at most exp(D/(p-1)*log(exp(1)/(p-1))) times the input norm. The actual truncated modular estimate, general layer cake, singular power integral, quantitative constant absorption, p-th-root conversion and all-input finite/Fatou extension are proved. At checkpoint1264 the current public export consumes the proved finite signed maximal theorem at constant6; a supplied RawFiniteSignedMaximalInput and its constant R are no longer hypotheses. No remaining source clause within the agreed conditional scope; no new strong maximal or layer-cake input is introduced. Theorem7.2's independent hypotheses remain explicit. The ergodic Corollary7.46 and Theorem1.5(ii) are now separately completed under their reviewed independent inputs.","For \(1<p\leq2\) and \(f\in\ell^p(\mathbb Z)\), \begin{align} \|A^*f\|_{\ell^p} \leq \exp\left(\frac{C}{p-1}\log\frac{e}{p-1} \right)\|f\|_{\ell^p}, \end{align} after enlarging the absolute constant \(C\)."

p:IWinput7,proposition,7.8,47,7,Quantitative maximal estimates near \(L^1\),4598,"conditional: All four source clauses are complete conditional implications for one common construction at every real Q>=2^k, r>=2 and k>=4. The literal B, epsilon and C_rk are retained; P<=3^Q, every a/q modulo one with q<=Q, all denominator bounds and full goodness are proved. The rough multiplier conclusion is an actual bounded operator on the entire integer lp space, with the exact finite-convolution Fourier kernel, uniqueness and norm <=C_rk times the actual full real Lp operator norm. The general full-Lp real/cyclic product bound and rank-one coefficient factorization are proved. Both major-arc sampling directions, actual unique interpolation on the full distributional integer lp Fourier-support class, the inverse-C_rk source inequality, and all finite-dimensional normed complex Shannon targets throughout 1<=p<=infinity are retained. Point sampling uses the standard continuous representative convention. General Tao construction, full adelic IW and full sampling theorems, including the explicitly described rough/full-class/finite-quotient realization bridges, remain independent unproved inputs. The earlier narrower endpoint results retain their own hypotheses.","Let \(r,k\in\mathbb N\), with \(r\geq2\) and \(k\geq4\), and let \(Q\geq2^k\). Put \begin{equation} \begin{gathered} p_r=\frac{2r}{2r-1}, \qquad B=C_*^{\,k^2Q^{1/(k-1/2)}},\\ \varepsilon=(2^{20}rB^{2r+8})^{-1}, \qquad C_{r,k}=(C_*r\log(2+k))^{C_*k}, \end{gathered} \end{equation} where \(C_*>1\) is a"

l:continuousestimates7,lemma,7.16,49,7,Quantitative maximal estimates near \(L^1\),4838,"conditional: Complete printed continuous lemma on the full Lp domain. One absolute positive constant is chosen before beta, p, J, signs and f. The actual signed-increment kernel has exactly the source multiplier and a full-Lp bound for every1<p<=2, arbitrary complex signs of modulus<=1 and every0<beta<=1. The maximum is over every real N>=2, represented as a proper extended-real supremum; a fixed countable dense set and proved scale continuity establish measurability, with a common almost-everywhere bound, finiteness and actual Lp membership. The literal real-scale kernel/Fourier identity and all annular L2/Hormander hypotheses are proved. The general one-sided Hardy–Littlewood and scalar Hormander theorems in their full-Lp forms remain unproved explicit independent inputs. No remaining source-specific clause within the agreed conditional scope. The full-domain general theorem interfaces and their exact published-to-Lean formulations remain external; they are not claimed to have been derived from the earlier restricted-domain inputs.","Uniformly in \(0<\beta\leq1\), \(J\geq1\), and \(|\sigma_j|\leq1\), one has, for \(1<p\leq2\), \begin{align} \left\| T_{\sum_{j=1}^J\sigma_j (\widehat{\widetilde M}_{2^j,\beta} -\widehat{\widetilde M}_{2^{j-1},\beta})}f \right\|_{L^p(\mathbb R)} &\ll \frac1{p-1}\|f\|_{L^p(\mathbb R)}, \\ \left\| \su"

p:orlicz-low,proposition,7.22,50,7,Quantitative maximal estimates near \(L^1\),5006,"conditional: The full actual dyadic IW low maximum is proved at every real Q>=2^k, uniformly in the cyclic measure of variation at most one and 0<beta<=1, for the real-Q geometric construction and for all integer lp inputs at p_r. The width, denominator bound and logarithmic cost are the literal real-Q quantities. A single harmless enlargement of the universal parameter constant from C to C^2 is made once. The arithmetic set, period, rational coverage through Q, denominator bound and goodness are retained; the maximal estimate uses exactly that set, period and real-Q cutoff. The adjusted-base proof and cost comparison are checked, as are all own symbol, smoothness, sampling, short-scale, narrow, remainder and all-input extension steps. The independent general standard inputs remain explicit; no current-paper conclusion is an external assumption. No own-paper deduction remains for this proposition. The recorded independent general construction, IW multiplier, sampling, continuous and signed-maximal theorems are explicit unformalized inputs, not proved Lean axioms.","Let \(r,k,Q,P,\Sigma_{\leq k},B,\varepsilon,p_r\), and \(C_{r,k}\) be as in Proposition~\ref{p:IWinput7}. Let \(\nu\) be a complex measure on \(\mathbb Z_P\) with \(\|\nu\|_{\mathrm{TV}}\leq1\), and let \(0<\beta\leq1\). Define \(L_N^{\nu,\beta}\) by \begin{align} \widehat{L_N^{\nu,\beta}}(\xi) = \s"

p:orlicz-hilo,proposition,7.30,53,7,Quantitative maximal estimates near \(L^1\),5322,"conditional: The complete real-Q high-low proposition is proved as an implication from the recorded independent standard

inputs. For every real Q>=2^k, one unchanged floor-Q arithmetic construction supplies both prime and ordinary-square decompositions at the literal real-Q cutoff. It retains period<=3^Q, rational coverage through Q, the literal denominator bound and goodness. Both actual countable low bounds hold on all integer lp inputs at p_r, with the exact logarithmic real-Q cost. Both actual high maxima share the same arithmetic set, period and selected Page datum and have a proved summed Q^(-1/4) L2 bound above the stated exponential starting scale. All operator identities and applicability are checked. The fixed absolute parameter constant is enlarged once from C to C^2; no width is rounded and no own-paper endpoint is an external premise. No own-paper deduction remains for this proposition. The recorded independent general construction, multiplier/sampling, continuous/signed-maximal, smooth multifrequency, Page/prime-distribution and scalar quadratic-Weyl inputs remain explicit and unproved. Their hypotheses are not Lean axioms or assertions of truth.","Using the assumptions and notation of Propositions~\ref{p:IWinput7} and \ref{p:orlicz-low}, put \begin{equation} D(r,k,Q)=rC_{r,k}^2\log(e+Q+r\log B). \end{equation} For dyadic \(N\geq N_0\), there are decompositions \[\widetilde A_{N,\Lambda}=L_N+H_N, \qquad \widetilde A_{N,\mathbb N^2}=L_N^\squar"

c:orlicz-ergodic,corollary,7.46,59,7,Quantitative maximal estimates near \(L^1\),6002,"conditional: Complete printed Corollary7.46 as an implication of the explicit independent inputs, for all three actual families and every invertible measure-preserving probability system. One common C >= 1 serves the strong exponential rate and source Orlicz gauge; one common modular multiplier is fixed before all systems, families, functions and levels. Every 1 < p <= 2 has the actual strong maximal norm with almost-everywhere finiteness and actual Lp membership. The proper extended maximum satisfies the source modular inequality. Every measurable Orlicz member at some positive scale has actual averages converging almost everywhere and in L1 to the same genuine L1 limit, with integrability of every average and both L1 seminorm/integral-norm convergence checked. Own truncation, rescaling, Cauchy/density, L1 operator and limit-identification deductions are proved. At checkpoint1264 the current public export consumes the proved finite signed maximal theorem at constant6; a supplied RawFiniteSignedMaximalInput and its constant R are no longer hypotheses. No remaining printed clause within the agreed conditional-formalization scope. The independent general Calderon strong/modular and bounded-class polynomial convergence inputs, including their unproved published-theorem/normalization bridges, remain explicit, as do the earlier Theorem7.2 independent inputs. Stronger standalone Section7 auxiliary ranges remain separately partial.","For \(1<p\leq2\), \begin{align} \|A_T^*f\|_{L^p(X)} \leq \exp\left(\frac{C}{p-1}\log\frac{e}{p-1} \right)\|f\|_{L^p(X)}. \end{align} Moreover, \begin{align} \mu\{A_T^*f>\lambda\} \ll \int_X\Psi_C\left(\frac{|f|}{\lambda}\right)\,d\mu, \qquad \lambda>0. \end{align} If $ \int_X\Psi_C(|f|/a)\,d\mu<\in"

t:l1badblackbox,theorem,8.1,60,8,Persistent universal \(L^1\)-badness of prime squares,6128,"conditional: Complete persistent-divergence adaptation from original general LaVictoire weak maximal failure and separately specified Sawyer and Conze principles. The arithmetic record contains actual cyclic residue sets, CRT, represented classes, odd coprime moduli, exact density infimum, little-o thickening, far-pair liminf and strict finite-product residue frequencies. For every nonatomic ergodic probability system and every infinite cutoff set, Lean produces a measurable integrable function and a measurable positive-measure set with no finite pointwise limit. Nonatomicity means measurable splitting, not merely null singletons. Positive moduli include the usual modulus-one convention; prime and cutoff indices are zero-based enumerations of the source positive-index sequences. No remaining persistent-divergence deduction within the agreed conditional scope. The original LaVictoire, Sawyer and Conze inputs and their precise published-to-Lean convention bridges are unproved.","Let (n_k) be an increasing sequence of natural numbers. Suppose that, for every $q>1$, there is a set $\Lambda_q\subset\{n_k\bmod q:k\geq1\}$ which is multiplicative under the Chinese remainder theorem: if $(q,r)=1$, then Λ_{qr} corresponds to $\Lambda_q\times\Lambda_r$. Suppose also that "

t:grankul,theorem,8.6,60,8,Persistent universal \(L^1\)-badness of prime squares,6170,"external_candidate: Quoted general deep theorem remains unproved. A precise interface now specifies arbitrary CRT residue families, uniform actual local correlations, one positive common exponent, constants chosen before primes/shifts, subpower reciprocal local density and growing spacing along odd squarefree moduli. The full joint cyclic gap conclusion is implemented. All its unit-square hypotheses and the actual joint and single-gap applications are proved conditional on that independent general input and Weil. The quoted general GK theorem and its published-to-Lean cyclic joint formulation bridge remain external and unproved. It is not needed for the repaired Theorem1.5(i) proof.","[Granville--Kurlberg \cite{GK08}] For each odd prime p, let $\Omega_p\subset\mathbb Z/p\mathbb Z$, put $r_p=|\Omega_p|/p$ and $s_p=r_p^{-1}$, and define Ω_q from the Ω_p, for squarefree q, by the Chinese remainder theorem. Suppose that, for every fixed $k\geq1$ and all distinct $0,"

l:quadratic-GK,lemma,8.8,61,8,Persistent universal \(L^1\)-badness of prime squares,6190,"conditional: Complete printed quadratic-residue correlation lemma as an implication of RawSplitQuadraticWeilInput, the general distinct-linear-factor character-sum bound. The literal finite residue correlation has explicit absolute error at most2*k*sqrt(p), actual density-normalized relative error at most3*k*3^k/sqrt(p), and the source GK error with c=1/3 and constant6*k*3^k. Quantification is uniform over every odd prime and every injective tuple of k shifts, including the source h0=0 case. All zero corrections, density factors, positivity, finite subset sums and reciprocal local-density subpower bounds are proved. No remaining printed correlation clause in the agreed conditional scope. The general Weil input remains unproved. The separate moment repair and badness deductions are now also complete; their inputs are separately recorded.","Let p be an odd prime and let \[\Lambda_p=\{x^2\pmod p:x\not\equiv0\pmod p\}. \] For every fixed $k\geq1$ and distinct $0,h_1,\ldots,h_{k-1}\pmod p$, \[N_k(\mathbf h,\Lambda_p)=\frac{p}{2^k}+O_k(p^{1/2}) =\left(\frac{p-1}{2p}\right)^kp\big(1+O_k(p^{-1/2})\big). \] Consequently \eqref{e:GK-hyp} h"

l:fromsiftedtop,lemma,9.2,63,9,Quantitative Goldbach-type estimate: reductions,6577,"proved: The complete first Section9 reduction is proved from its ordinary range hypotheses. The primitive sum-of-two-squares criterion is now a project theorem, not an additional input. Actual finite sifted and good representation sets and the uniform O(N^epsilon) exception are retained. At1262: Every Section9 numbered source claim and its final quantitative theorem is complete in the agreed scope. All elementary arithmetic reductions are now proved without an extra primitive two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is constructed. Only the explicit independent analytic inputs remain for the circle-method/sieve/headline estimates. The user is applying previous manuscript edits; no application is assumed and original sources are unchanged.","For every $\varepsilon>0$, \begin{align} |\{r\in\mathcal P:n-r\in\mathbb P^2\}| \geq S(\mathcal A_n,\mathbb P_{3,n},N^2)-O_\varepsilon(N^\varepsilon). \end{align}"

l:truncationT,lemma,9.3,64,9,Quantitative Goldbach-type estimate: reductions,6605,"proved: The full source truncation identity is proved with an explicit nonnegative error bounded by O(N^epsilon), including repeated3 mod4 prime factors and the actual source factorization set. The primitive criterion is internally proved; only the normal source range hypotheses remain. At1262: Every Section9 numbered source claim and its final quantitative theorem is complete in the agreed scope. All elementary arithmetic reductions are now proved without an extra primitive two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is constructed. Only the explicit

independent analytic inputs remain for the circle-method/sieve/headline estimates. The user is applying previous manuscript edits; no application is assumed and original sources are unchanged.","For every \(\varepsilon>0\), \begin{align} S(\mathcal A_n,\mathbb P_{3,n},z) - |\{r\in\mathcal P:n-r\in\mathbb P^2\}| = |T_n|+O_\varepsilon(N^\varepsilon), \end{align} where \begin{align} T_n= \left\{ r-1=2up_1p_2: \begin{array}{l} r\in\mathbb P,\quad n-r\in\mathbb P^2,\\ z\leq p_2\leq p_1,\quad p_i"
l:upperreduction,lemma,9.7,65,9,Quantitative Goldbach-type estimate: reductions,6706,"proved: For the user-corrected closed-cutoff L, the entire actual upper-sifted inclusion, exact finite cardinal upper bound with error omega(n-1), and uniform O_epsilon(N^epsilon) bound are proved. No analytic, sieve, primitive two-square or own-paper endpoint is assumed. All eight closed cutoff occurrences are verified in the latest upload.","For every $\varepsilon>0$, \begin{align} |T_n| \leq\sum_{\ell\in L_n} S(M_n(\ell),W_{\ell,n},z_\ell)+O_\varepsilon(N^\varepsilon). \end{align}"
c:mastersievereduction,corollary,9.9,65,9,Quantitative Goldbach-type estimate: reductions,6758,"proved: The full source master sieve reduction is proved from ordinary source hypotheses and the adopted closed multiplier cutoff. Its exact finite error is at most2 omega(n-1), and its uniform O(N^epsilon) consequence is exported. No primitive-criterion or analytic assumption is needed for this arithmetic reduction. At1262: Every Section9 numbered source claim and its final quantitative theorem is complete in the agreed scope. All elementary arithmetic reductions are now proved without an extra primitive two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is constructed. Only the explicit independent analytic inputs remain for the circle-method/sieve/headline estimates. The user is applying previous manuscript edits; no application is assumed and original sources are unchanged.","For every $\varepsilon>0$, \begin{align} |\{r\in\mathcal P:n-r\in\mathbb P^2\}| &\geq S(\mathcal A_n,\mathbb P_{3,n},z)-\sum_{\ell\in L_n} S(M_n(\ell),W_{\ell,n},z_\ell) -O_\varepsilon(N^\varepsilon). \end{align}"
l:circmethod,lemma,9.10,65,9,Quantitative Goldbach-type estimate: reductions,6783,"conditional: Complete source circle-method mean-square approximation for every A,delta>0, with B0,C,K,N0 chosen before N and every arithmetic family. Covers all B>=B0, exact strict real L<N^(2-delta), positive ell,k with k<V(ell), every coprime residue class, arbitrary complex coefficients of norm<=1, and all n<N^2. The stronger uniform cutoff statement holds for every 2<=U<=N,W>=2. The final source theorem removes cutoffs using the proved equation-imposed bounds, and uses the actual finite prime-pair count, actual local Euler factor G_R and actual autocorrelation singular integral H_R. Fourier inversion, all three error identifications, shared constants, minor estimate, major replacement, arithmetic completion and smoothing are consumed internally. Its only unformalized hypotheses are independent ordinary SW prime counts, ordinary unweighted BV prime-count distribution, and uniform raw Ren/Ghosh quadratic estimates. No own-paper conclusion is assumed. At1212: Completed all Section10 source statements and the full circle-method implication; the three independent raw deep inputs remain explicit and unproved. At1213: Completed every Section10 source statement and the full source circle-method implication, including the original smooth compact seed and exact normalized integral. Only the three agreed independent raw deep inputs remain for this circle-method implication. None within the full source circle-method implication. The three independent raw distribution/exponential-sum inputs remain unproved; Section11 and the headline Goldbach result remain separate work.","[Bombieri--Vinogradov approximation] Let \(A,\delta>0\) and \(L_0<N^{2-\delta}\). There are sufficiently large constants \(B=B(A,\delta)\) and \(C=C(A,\delta)\) such that the following holds. Put \[R=(\log N)^C,\qquad \eta_N(\theta)=\eta\left(\frac{N^2\theta}{R}\right), \] and suppose that $V_\ell\"
p:sieveneedlower8,proposition,9.17,67,9,Quantitative Goldbach-type estimate: reductions,6898,"conditional: Full source lower-sieve proposition, including the actual representation sequence, original X_n and Euler product, coefficients before n, a common error tending to zero, and the N^4(log N)^(-A) mean-square remainder bound. The pointwise theorem holds throughout the source retained range (indeed all n=12 mod24). General classical sieve/Mertens/function-continuity and ordinary SW/BV/Ren-Ghosh inputs remain explicit and unproved. At1229: Common cutoff compatibility for the circle-method and full lower-sieve estimates is proved for every requested lower bound on C; main-term size remains to be joined. At1230: The full source main-term size and the entire lower-bound side are complete conditionally, including an exponent independent of C, uniform smoothing, one common large cutoff and finite error-to-exception deductions. At1230 the source main-term size and the full lower sieve are proved jointly for the same C>=A0+6; finite positive-count and exceptional-cardinality deductions are checked. At1258: All Section11 numbered claims are complete in the agreed conditional scope for the explicitly supplied corrected presieving statement. The original weaker statement is not proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic mean-square saving. The final Goldbach theorem remains the next deduction.","[Lower sieve] For $N^2(\log N)^{-A_0}\leq n<N^2$, $n\equiv12\pmod{24}$, \begin{align} S(\mathcal A_n,\mathbb P_{3,n},z) \geq X_n\Theta_n(z)\bigl(f_{1/2}(9/8)+o(1)\bigr) +\mathcal E_1(n), \end{align} where \begin{align} \sum_{n<N^2}|\mathcal E_1(n)|^2 \ll_{A_0,K} N^4(\log N)^{-K}. \end{align}"
p:sieveneedupper8,proposition,9.20,67,9,Quantitative Goldbach-type estimate: reductions,6922,"conditional: The full source upper sieve is complete in uniform epsilon form, with the exact c_(9/8) F_1(2) W(9/8) coefficient, original actual main term and closed multiplier set. All coefficients precede n; source divisor counts, refined preliminary/outer dimensions, uniform varying levels, the shifted double remainder sum, its circle-method embedding and the fixed-sieve O(N^(1/4)) correction are proved. The total error has arbitrarily strong logarithmic mean-square saving. Only independent general SW, BV, Ren/Ghosh, classical one-stage sieve, effective multiplicative mean and Mertens inputs and general sieve normalizations remain unproved; no own-paper endpoint is assumed. At1257: Full upper-sieve proposition p:sieveneedupper8 complete in uniform epsilon form from explicit independent classical inputs, with the exact coefficient and arbitrary logarithmic mean-square saving. The lower analytic estimate and both remainder transports are available at a shared prescribed cutoff. The final joint Section11 assembly and manuscript synchronization are next. At1258: All Section11 numbered claims are complete in the agreed conditional scope for the explicitly supplied corrected presieving statement. The original weaker statement is not proved and must be replaced in the user manuscript. The theorem allows B≥0 and 0≤U≤N, with arbitrary W and residues, so it is stronger than the stated ranges. Explicit bound K N⁴(log N)^(-A), K=Z²(256/log 2), Z=(2P+3)/log 2, C₀=3A+4d+26. Finite Abel, prime-power removal, halving reconstruction, scale transfer, eventual cutoffs, source progression energy and Bessel are proved. Only the already recorded independent raw Ren/Ghosh input is assumed. The independent raw UniformRenGhoshInputs remains explicit and unproved. The source hybrid minor conclusion and all conversion steps are discharged; no internal own-paper hypothesis remains.","Under the hypotheses of Lemma~\ref{l:circmethod}, uniformly for \(2\leq U\leq N\) and \(2\leq W\leq N^2\), \begin{align} \sum_{n<N^2}\left| \int_{\mathfrak m}P_U(\theta) \sum_{\ell<L_0}\sum_{k<V_\ell} d_{k,\ell}F_{k,\ell,W}(\theta)e(-n\theta)\,d\theta \right|^2 \ll_{A,\delta}N^4(\log N)^{-A}. \end{a"
l:positiveH9,lemma,10.12,70,10,Quantitative Goldbach-type estimate: the circle method,7266,"proved: At1176: The actual normalized autocorrelation cutoff has a proved positive denominator, exact convolution integral, eta(0)=1 and real nonnegative inverse Fourier transform. At1177: The scaled actual eta_N and its square have proved real nonnegative inverse Fourier transforms and exact compact support inherited from the seed. At1178: The actual eta is real, even, bounded by1, has zero derivative at0 and satisfies the full global quadratic source cutoff bound. At1179: Two-sided absolute integrability and an explicit L1 estimate are proved from the exact finite-scale bound and inverse-three-halves tail. At1180: The exact cutoff-weighted Fourier integral is a proved positive average of the inverse kernel, with Fubini integrability discharged. At1181: The actual source singular integral is proved real nonnegative, uniformly in all positive ell and every real n, including the empty-domain branch. At1182: The actual Euclidean product and smoothed integrand are globally integrable, and the exact source singular integral satisfies a proved uniform O(N) bound for all positive ell. At1183: The full quantitative real-line smoothing error bound is proved with absolute constant6 and every integrability condition discharged. At1184: The actual smoothed and unsmoothed source integrals satisfy the full uniform O(N/sqrt(R)) comparison, with all integrability and empty-domain branches proved. At1185: The actual quadratic affine density is globally integrable and has the proved exact product Fourier transform, including the scale factor. At1186: The genuine logarithmic quadratic density is continuous and integrable, with its exact source product Fourier transform proved and endpoint exceptional sets checked. At1187: The full source l:positiveH9 is proved: the exact autocorrelation cutoff, real nonnegative smoothed singular integral, its exact printed one-variable H_ell domain, and the uniform O(N/sqrt(R)) comparison, including all positive ell and empty-domain cases. There is no independent analytic input for this lemma. At1213: Completed every Section10 source statement and the full source circle-method implication, including the original smooth compact seed and exact normalized integral. Only the three agreed independent raw deep inputs remain for this circle-method implication. None. Positivity and the comparison with the exact printed one-variable domain are proved for the actual source cutoff and integrals, without extra external analytic input.","Uniformly in \(\ell,U,W\) and \(n<N^2\), \[H_{\ell,R}(n;U,W)\geq0, \qquad H_{\ell,R}(n;U,W) = H_\ell(n;U,W)+O(NR^{-1/2}), \] where \[H_\ell(n;U,W) = \int_{\substack{2\leq u\leq U\\ 2\leq(n-u^2)/\ell\leq W}} \frac{du}{\log u\log((n-u^2)/\ell)}. \]"
l:majorapproximation9,lemma,10.15,71,10,Quantitative Goldbach-type estimate: the circle method,7351,"conditional: At1126: The exact lcm-fibre divisor bound and weighted progression-error reindexing for the major arcs are proved. At1137: Exact strict-cutoff reduction and a uniform one-term endpoint error are proved for the actual progression sums. At1138: The exact prime counting and logarithmic-integral progression models, derivatives and lower-endpoint identities are proved. At1139: The actual prime-count discrepancy is transported through every smooth unit phase with an explicit quantitative error, including the lower prime endpoint. At1140: Exact positive-phase linear and quadratic partial-summation errors are proved from ordinary prime-counting discrepancies, with signs and totient normalizations checked. At1141: The actual prime-square major-arc model and explicit nonunit/count-discrepancy error are proved with the exact source sign and normalization. At1142: The fixed-q lcm fibre bound and complete reduction to ordinary unweighted modulus-distribution errors are proved. At1143: The compatible lcm residue sets, q-cardinality bound and generalized CRT existence/converse are proved for arbitrary positive moduli. At1144: The exact Upsilon coefficient for the actual compatible lcm residue classes is proved, including both signs and totient factors. At1145: The exact independent ordinary prime-count SW/BV boundaries are implemented; real-error equivalence, square-model numeric bound and logarithmic absorption are proved. At1146: The full uniform source SW prime-square major approximation is a complete deduction from the independent ordinary prime-count SW input. At1147: Exact prime progression residue fibres and positive rational-phase grouping are proved for the actual finite sums. At1148: The actual source linear model and all nonunit/strict-endpoint errors are proved from ordinary lcm-modulus prime-count discrepancies. At1149: The actual strict source J integral, clamped prime cutoff, and uniform numeric linear model error are matched exactly. At1150: Actual BV row approximation is proved under the independent ordinary unweighted BV input, with individual progression cutoffs and all finite exceptional terms retained. At1151: The printed source ranges imply the ordinary BV level and comparable logarithmic saving, with a threshold uniform in every active ell. At1152: The actual source row-scale sum and coefficient-family cardinality square bound are proved, including all empty-cutoff cases. At1153: Every retained prime endpoint/nonunit term is absorbed uniformly from the exact printed source ranges, using a proved power saving. At1154: The full uniform source BV progression-error norm sum is complete under the independent ordinary unweighted BV input, with all individual cutoffs and finite errors included. At1155: Exact source major-set geometry,

normalized measure, wrap-around lifts, pairwise disjointness and eventual separation are proved. At1156: Measurable local coordinates and genuine Euclidean model regularity and norm bounds are proved for the circle Bessel assembly. At1157: The exact source major models are constructed on the circle, with proved localization and all-Lp regularity and the required square size bound. At1158: Both full SW/BV major estimates now hold for the constructed exact source circle models, uniformly in every printed parameter. At1159: The restricted measurable Bessel inequalities and two-model major-arc mean-square assembly are proved. At1160: The actual weighted source coefficient identity, model Lp bounds and complete logarithmic mean-square budget are proved. At1161: The full source major-arc mean-square approximation l:majorapproximation9 is complete under ordinary SW and BV, uniformly in all printed data, with strict endpoints and finite errors discharged. No unmatched clause remains in this lemma. The independent ordinary SW and BV proofs remain external; apply docs/MAJOR_ARC_PROOF_REPLACEMENT.tex to correct the endpoint bookkeeping in its source proof.","Uniformly for \(2\leq U\leq N\) and \(2\leq W\leq N^2\), \begin{align} \sum_{n<N^2}\left| \sum_{\ell<L_0}\sum_{k<V_\ell}d_{k,\ell} \int_{\mathfrak M} \bigl(P_UF_{k,\ell,W} -P_U^{(0)}F_{k,\ell,W}^{(0)}\bigr)(\theta) e(-n\theta)\,d\theta \right|^2 \ll_{A,\delta}N^4(\log N)^{-A}. \end{align}" l:arithmeticcoefficients9,lemma,10.20,74,10,Quantitative Goldbach-type estimate: the circle method,7612,"proved: Completed Section 3 identities are reusable; this full statement is not counted as partial merely because it cites them. At1162: The actual inclusive R-smooth arithmetic series is absolutely summable, equals the source finite Euler product and admits an exact finite cutoff/tail split. At1163: The genuine Euclidean source integrals have proved quadratic and linear frequency decay, with explicit constants and all cutoffs retained. At1164: Unconditional reciprocal-totient harmonic estimates, including arbitrary divisor progressions, and the exact gcd divisor expansion are proved. At1165: The full source arithmetic-family harmonic estimate is proved unconditionally with explicit divisor exponent2 and constant9 exp(2). At1166: Exact arbitrary-multiplier coefficient identities and the uniform odd-prime bound8 gcd(p,k*ell)/p are proved. At1168: The genuine coefficient has a uniform prime-power gcd bound, with every two-adic exponent handled explicitly. At1169: General-modulus source coefficient decay tau(q)^9 gcd(q,k*ell)/q and principal Gauss decay tau(q)^3/sqrt(q) are proved unconditionally. At1170: The actual weighted source arithmetic-family and finite denominator-tail bounds are proved; the full source arithmetic and completion lemmas remain open with explicit remaining clauses. At1171: Normalized finite unit averages are proved invariant under reduction to every divisor modulus. At1172: Primitive progression exponential cancellation and the coprime norm bound are proved from actual finite unit sums. At1173: The actual Upsilon coefficient is an exact lcm-unit expectation and satisfies exact simultaneous frequency/denominator reduction. At1174: The actual Upsilon coefficient has the proved sharp gcd/divisor decay tau(q) gcd(q,k*ell)/q. At1175: The full source arithmetic-coefficient lemma is proved: absolute convergence, the all-prime infinite local Euler series and its exact source G_R value, all three individual bounds with the common divisor exponent9, and the complete real-cutoff harmonic family estimate. There are no external inputs for this lemma. None. All clauses are proved under the source hypotheses; no extra external mathematical input.","The series \[\sum_{\substack{q\geq1\\P^+(q)\leq R}} \mathfrak G_q(\ell,k,n) \] converges absolutely and satisfies \begin{align} \sum_{\substack{q\geq1\\P^+(q)\leq R}} \mathfrak G_q(\ell,k,n) &= \prod_{p\leq R} \left(1+\sum_{\nu\geq1} \mathfrak G_{p^\nu}(\ell,k,n)\right) =G_R(\ell,k,n), \end{align} " l:majorcompletion9,lemma,10.24,75,10,Quantitative Goldbach-type estimate: the circle method,7713,"proved: Complete actual source major-completion mean-square estimate for every A,delta>0, all sufficiently large C, all B>=0 and sufficiently large N, exact strict real arithmetic cutoffs, arbitrary coprime residue representatives and coefficients of norm at most one, and every 2<=U<=N,W>=2. Constants and thresholds precede N and all families. The actual major models, Euler factor G_R and singular integral H_R are used. The sharp cutoff comparison, separated additional denominators, finite arithmetic completion and quantitative Rankin tail are proved internally. No independent deep input is used. The source W<=N^2 restriction is unnecessary. The proof uses a weaker intermediate power of R that yields the same prescribed logarithmic saving after increasing C. At1211: Completed the full source major-completion lemma without external deep inputs. None within the source major-completion statement. The independent SW/BV replacement and Ren/Ghosh estimates belong to separate lemmas.","Under the hypotheses of Lemma~\ref{l:circmethod}, uniformly for \(2\leq U\leq N\) and \(2\leq W\leq N^2\), \begin{align} & \sum_{n<N^2}\left| \sum_{\ell<L_0}\sum_{k<V_\ell}d_{k,\ell} \left(\int_{\mathfrak M} P_U^{(0)}(\theta)F_{k,\ell,W}^{(0)}(\theta)e(-n\theta)\,d\theta - \frac{G_R(\ell,k,n)}{\ell" l:fixedsievesets10,lemma,11.2,78,11,Quantitative Goldbach-type estimate: sieve arguments,8013,"proved: Complete lower and upper fixed-sieve comparison, with actual sieve prime sets and actual closed multiplier set. The lower inequality is proved by inclusion, including the prime3 boundary. The upper comparison uses an exact finite exceptional-pair inclusion and the bound sum over p|n of tau(n-p^2-1) <= K_epsilon N^epsilon. One positive constant is chosen before N,n,z. Holds for every N>=1,0<n<=N^2 and every real z, hence the full retained source range. No deep input is used. At1215: The full source fixed-sieve comparison is proved without deep inputs. The local density, presieving and final sieve estimates remain open. None within the source fixed-sieve comparison lemma.","For every \(\varepsilon>0\), \begin{align} S(\mathcal A_n,\mathbb P_{3,n},z) &\geq S(\mathcal A_n,\mathbb P_3,z), \\ \sum_{\ell\in L_n}S(M_n(\ell),W_{\ell,n},z_\ell) &\leq \sum_{\ell\in L}S(M_n(\ell),W_\ell,z_\ell) +O_\varepsilon(N^\varepsilon). \end{align}" l:lowerlocaldensity,lemma,11.6,79,11,Quantitative Goldbach-type estimate: sieve arguments,8098,"proved: At1216: Proved the exact lower sieve sequence/progression count and its actual circle-method remainder decomposition. The full fixed-sieve comparison remains proved; local densities and later sieve conclusions remain open. At1219: Actual unit-square root counts, both candidate prime-density bounds including p=5, and the explicit multiplicative sieve function are proved without deep inputs. Full local-density normalization is the next internal obligation. At1220: Proved the conductor-sensitive coefficient identity, all actual prime-factor cases, the exact factors at2 and3, residue invariance, and normalized prime adjunction without division by the global base factor. Full local-density source closure is reserved for the final product and CRT assembly. At1221: complete actual normalized Euler-product factorization, exact source CRT residues, inclusive prime cutoff, multiplicativity and all density bounds are proved without external inputs. The upper base factor may vanish; no division by it is used. At1221: Both full source local-density lemmas are proved without new external inputs: exact original Euler normalization, inclusive cutoff, lower quotient identification, source CRT specializations, upper multiplicativity and p=5, with common zero upper base factors retained. Presieving and the later sieve estimates remain open. None within the source statement and retained admissible context.","For \(p>3\), \(p\equiv3\pmod4\), \begin{align} \frac{\omega_n(p)}p = \begin{cases} \displaystyle \frac{\rho_p(n-1)}{p-1-\rho_p(n)},&p\leq R,\\[7pt] \displaystyle\frac1{p-1},&p>R. \end{cases} \end{align} In particular, for \(p\geq7\), \(0\leq\omega_n(p)/p\leq2/(p-3)<1\)." l:upperlocaldensity,lemma,11.8,80,11,Quantitative Goldbach-type estimate: sieve arguments,8159,"proved: At1217: Proved the exact upper sieve sequence/progression count, including all prime exclusions, source multiplier arithmetic and residue independence from n. Local-density factorization and the later analytic sieve estimates remain open. At1219: Actual unit-square root counts, both candidate prime-density bounds including p=5, and the explicit multiplicative sieve function are proved without deep inputs. Full local-density normalization is the next internal obligation. At1220: Proved the conductor-sensitive coefficient identity, all actual prime-factor cases, the exact factors at2 and3,

residue invariance, and normalized prime adjunction without division by the global base factor. Full local-density source closure is reserved for the final product and CRT assembly. At1221: complete actual normalized Euler-product factorization, exact source CRT residues, inclusive prime cutoff, multiplicativity and all density bounds are proved without external inputs. The upper base factor may vanish; no division by it is used. At1221: Both full source local-density lemmas are proved without new external inputs: exact original Euler normalization, inclusive cutoff, lower quotient identification, source CRT specializations, upper multiplicativity and p=5, with common zero upper base factors retained. Presieving and the later sieve estimates remain open. None within the source statement and retained admissible context.","There is a multiplicative function \(\omega_n(\ell,\cdot)\), defined on square-free integers supported on \(W_\ell\), such that \begin{align} \frac{G_R(\ell,12d,n-1)}{\phi(12d)} = \frac{G_R(\ell,12,n-1)}{\phi(12)} \frac{\omega_n(\ell,d)}d . \end{align} For \(p\nmid12\ell\), its factors are \begin{al" l:presieving,lemma,11.13,81,11,Quantitative Goldbach-type estimate: sieve arguments,8273,"conditional: The corrected two-range presieving statement is a complete implication from the explicit independent general one-stage sieve inputs. The exact source matched is the separately supplied Section11_Reconciled.tex: X>=0, g(1)=1, fixed R=(log N)^C, R+1<=z<=D1<=N^A, refined1+K/logw dimension bounds, and the preliminary endpointR+1. Coefficients precede the density/sequence and n, have absolute value<=1 and exact level support; the common relative error tends to zero. The literal original weaker manuscript statement is not claimed proved; replacement is required in the user manuscript. No original source file was changed. At1258: All Section11 numbered claims are complete in the agreed conditional scope for the explicitly supplied corrected presieving statement. The original weaker statement is not proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic mean-square saving. The final Goldbach theorem remains the next deduction. At1265 the uploaded human-readable statement is reviewed directly: D0<D follows from its level chain, and the inline interval prime conditions are proved equivalent in Lean. The corrected mathematical hypotheses are verified as present in the actual upload; no presieving replacement remains outstanding.","Suppose that \begin{align} |\mathcal F_d|=Xg(d)+r_d, \end{align} where \(X\geq0\), and \(g\) is multiplicative on the square-free integers supported on a fixed set of primes \(\mathfrak P\), with \(g(1)=1\) and \(0\leq g(p)<1\). Fix \(C,A>0\), set \(R=(\log N)^C\), \(D_0=\exp((\log\log N)^3)\), and " l:wumatomakisum,lemma,11.19,85,11,Quantitative Goldbach-type estimate: sieve arguments,8636,"conditional: Complete source weighted upper main-term comparison, in uniform epsilon form, with the actual multiplier set, local factors, finite Euler products and singular integrals. For every A>0, every fixed C>=A+24 and eta>0, one threshold in N works for all n=12 mod24 with N^2(log N)^(-A)<=n<N^2. The coefficient is exactly c_(9/8) W(9/8)+eta. Strong multiplicativity, the uniform mean instantiation, both finite Abel arguments, W identity, all small-denominator and endpoint terms, moving logarithms, integration, smoothing and relative errors are proved. Only the independent generic effective mean-value corollary and classical fixed-progression Mertens bounds remain explicit unproved hypotheses. The source lemma statement is unchanged; two proof replacements are supplied but not applied. At1252: The full source weighted upper main-term comparison l:wumatomakisum is complete as a checked implication from independent generic effective mean-value and classical Mertens inputs, with the exact printed constant, actual source definitions, uniform retained-range quantifiers, and every summation, integration and relative-error obligation discharged.","Let \(\alpha=9/8\). Uniformly in the range \eqref{e:nrange10}, \begin{align} \sum_{\ell\in L}X_n(\ell)\Theta_{n,\ell}(z_\ell) \leq \bigl(c_\alpha\mathcal W(\alpha)+o(1)\bigr) X_n\Theta_n(z), \qquad c_\alpha=\frac{16e^{-\gamma/2}}{\sqrt{\pi\alpha}}. \end{align} Here \(\mathcal W(\alpha)\) is the inte"

1.5,theorem,t:pet,Persistent L1 badness and near-L1 maximal bound,Badness and
convergence,conditional,"Both parts are complete conditional implications. Part(i): the actual
enumerated prime squares are persistently universally L1-bad on every truly nonatomic ergodic
measure-preserving probability system, with every infinite cutoff set and an actual measurable
positive-measure divergence set. CRT, Dirichlet representation, correlation counts, large-prime block
construction, all moment/thickening/difference limits, uniform square-root fibers and the
fixed-progression PNT pushforward are proved. The original badness theorem, Sawyer, Conze, general Weil
and fixed-progression PNT remain separate unproved general inputs. Granville–Kurlberg is not used by
part(i). A checked moment proof replaces the source strict finite-fraction argument, which has an exact
kernel counterexample. Part(ii) is a complete conditional implication: an absolute positive constant
before every invertible measure-preserving probability system, every 1 < p <= 2 and every Lp input; the
proper actual maximum over the first m prime squares for all m >= 1 is finite almost everywhere, belongs
 to Lp and has the exact displayed exponential norm bound. The prime-counting/enumeration normalization,
 finite sums, first-prime case and equality of both full maxima are proved with no PNT or enumeration
input. The proof uses the already proved Corollary7.6 and the precise independent general strong
Calderon input, plus the earlier Theorem7.2 independent inputs. It does not use the bounded-class
convergence input. At checkpoint1264 the current public export consumes the proved finite signed maximal
 theorem at constant6; a supplied RawFiniteSignedMaximalInput and its constant R are no longer
hypotheses.",No remaining source clause within the agreed conditional scope. General inputs and their
exact convention bridges remain unproved. The user confirmed the three Section8 edits; the selected
project manuscript now contains the agreed moment proof.,LAVICTOIRE; WEIL; PROGRESSION_ESTIMATE;

1.6,theorem,t:repmotthm,Quantitative Goldbach-type exceptional set,Goldbach and sieve,conditional,"The
full quantitative exceptional-set theorem is complete: for every A>0, the actual exceptional set of
positive n<X congruent12 mod24 without a prime plus a square-of-prime representation whose first prime
is a primitive sum of two squares plus1 has size O_A(X(log X)^(-A)), eventually at every real X. The
representation and exceptional-set membership are exact. The common-cutoff Section11 estimates, positive
 numerical gap, arbitrary logarithmic mean-square saving, all arithmetic losses, small n and the passage
 from N^2 to real X are discharged. Explicit independent general SW, BV, Ren/Ghosh, one-stage sieve,
effective multiplicative mean, Mertens, normalized sieve values/continuity and primitive two-square
criterion remain unproved theorem parameters. No own-paper endpoint is a hypothesis. At1259: Section11
and the final quantitative Goldbach theorem are complete in the agreed conditional scope, using the
supplied corrected presieving statement. Every paper endpoint is discharged; only explicit independent
general classical inputs and their normalizations remain unproved. Original manuscripts are unchanged
and the supplied Section11 replacements still require user application. No additional completion credit
is claimed for stronger unnumbered assertions in alternate proof routes. At1261: Proved the full

PrimitiveTwoSquaresCriterion from pinned Mathlib and elementary algebra, and proved W(alpha) convergence/nonnegativity for every alpha>1. Constructed a concrete nonzero compactly supported smooth seed. The next stage exports the Section9 arithmetic and headline statements without the former criterion or seed hypotheses, then reconciles the stale Section9 map. User manuscript edits remain in progress. At1262 the final endpoint is exported from GoldbachSection11Inputs alone: the primitive two-square criterion is proved internally and a fixed nonzero smooth compact seed is constructed. The real-X bound and zero exceptional density need no separate arithmetic or seed assumption. At1262: Every Section9 numbered source claim and its final quantitative theorem is complete in the agreed scope. All elementary arithmetic reductions are now proved without an extra primitive two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is constructed. Only the explicit independent analytic inputs remain for the circle-method/sieve/headline estimates. 5.10,lemma,l:sparserecursion,Sparse recursion from local estimates,Sparse estimates,proved,"The actual
prime-square finite stopping construction, disjoint components, real-radius admissibility, exact kernel
localization, terminating cost recursion and actual sparse major subsets are proved, with a proved
all-cutoff reduction for the original averages. A general finite recursive-cost implication is also
proved. The complete general dyadic implication is now proved for arbitrary positive compact-support
kernels, every fixed odd support dilation, arbitrary Psi, the full untruncated maximum and genuine
quarter-sparse major sets. The uniform bound and finite approximation of the full maximum are deduced
from the local hypothesis. The local hypothesis is imposed only on maps admissible on the whole
interval; an extension argument proves the needed restricted version.",No own-paper deduction remains
under the accepted dyadic and independent-admissibility-constant conventions. The proof constructs
actual sparse sets and the full maximum from the stated local hypothesis; no additional analytic
estimate is assumed.,,finiteSparseRecursion; laminarSparseRecursion; primeAnnularSparse_from_local;

7.2,theorem,t:orlicz-maximal,Quantitative Orlicz maximal theorem,Orlicz and ergodic
estimates,conditional,"Complete printed Theorem 7.2 as an implication of explicit independent standard
inputs: all three actual families (von Mangoldt squares, ordinary squares, unweighted prime squares),
every integer cutoff N >= 2, every complex finitely supported function and positive level, with common
absolute C, C0 and K >= 1. All three conclusions are proved, including finite level sets: the truncated
modular bound, unrestricted modular bound and restricted bound for every finite F and t >= 1. The final
theorem is stated with literal sums over all integers and finite support, using the actual integral
gauge. The ordinary branch derives the actual discrete circle-model error, maximal comparison, low/high
restricted bound and full-cutoff reconstruction from the independent scalar Weyl input and general IW
inputs; no own restricted or high/low conclusion is assumed. The unweighted-prime transfer uses proved
Mathlib Chebyshev bounds without a new PNT input. At checkpoint1264 the current public export consumes
the proved finite signed maximal theorem at constant6; a supplied RawFiniteSignedMaximalInput and its
constant R are no longer hypotheses.",No remaining clause of Theorem7.2 or Corollaries7.6/7.46 within
the agreed conditional scope. The explicitly recorded independent inputs and their published-theorem
bridges remain unformalized. Stronger standalone auxiliary parameter/full-generality ranges and later
badness/sieve results remain separately tracked.,QUANTITATIVE_IW; GENERAL_VARIATION_SAMPLING;

7.8,proposition,p:IWinput7,Quantitative Ionescu-Wainger application,Orlicz and ergodic
estimates,conditional,"All four source clauses are complete conditional implications for one common
construction at every real Q>=2^k, r>=2 and k>=4. The literal B, epsilon and C_rk are retained; P<=3^Q,
every a/q modulo one with q<=Q, all denominator bounds and full goodness are proved. The rough
multiplier conclusion is an actual bounded operator on the entire integer lp space, with the exact
finite-convolution Fourier kernel, uniqueness and norm <=C_rk times the actual full real Lp operator
norm. The general full-Lp real/cyclic product bound and rank-one coefficient factorization are proved.
Both major-arc sampling directions, actual unique interpolation on the full distributional integer lp
Fourier-support class, the inverse-C_rk source inequality, and all finite-dimensional normed complex
Shannon targets throughout 1<=p<=infinity are retained. Point sampling uses the standard continuous
representative convention. General Tao construction, full adelic IW and full sampling theorems,
including the explicitly described rough/full-class/finite-quotient realization bridges, remain
independent unproved inputs. The earlier narrower endpoint results retain their own
hypotheses.",,QUANTITATIVE_IW; FULL_DOMAIN_ADELIC_IW;

7.16,lemma,l:continuousestimates7,Uniform continuous annular increment and maximal estimates,Orlicz and
ergodic estimates,conditional,"Complete printed continuous lemma on the full Lp domain. One absolute
positive constant is chosen before beta, p, J, signs and f. The actual signed-increment kernel has
exactly the source multiplier and a full-Lp bound for every1<p<=2, arbitrary complex signs of modulus<=1
 and every0<beta<=1. The maximum is over every real N>=2, represented as a proper extended-real
supremum; a fixed countable dense set and proved scale continuity establish measurability, with a common
 almost-everywhere bound, finiteness and actual Lp membership. The literal real-scale kernel/Fourier
identity and all annular L2/Hormander hypotheses are proved. The general one-sided Hardy–Littlewood and
scalar Hormander theorems in their full-Lp forms remain unproved explicit independent inputs.",No
remaining source-specific clause within the agreed conditional scope. The full-domain general theorem
interfaces and their exact published-to-Lean formulations remain external; they are not claimed to have
been derived from the earlier restricted-domain
inputs.,FULL_DOMAIN_CONTINUOUS_STANDARDS,continuousAnnularSignedMultiplier_L2;

7.22,proposition,p:orlicz-low,Quantitative Orlicz low estimate,Orlicz and ergodic
estimates,conditional,"The full actual dyadic IW low maximum is proved at every real Q>=2^k, uniformly
in the cyclic measure of variation at most one and 0<beta<=1, for the real-Q geometric construction and
for all integer lp inputs at p_r. The width, denominator bound and logarithmic cost are the literal
real-Q quantities. A single harmless enlargement of the universal parameter constant from C to C^2 is
made once. The arithmetic set, period, rational coverage through Q, denominator bound and goodness are
retained; the maximal estimate uses exactly that set, period and real-Q cutoff. The adjusted-base proof
and cost comparison are checked, as are all own symbol, smoothness, sampling, short-scale, narrow,
remainder and all-input extension steps. The independent general standard inputs remain explicit; no
current-paper conclusion is an external assumption.","No own-paper deduction remains for this
proposition. The recorded independent general construction, IW multiplier, sampling, continuous and
signed-maximal theorems are explicit unformalized inputs, not proved Lean axioms.",QUANTITATIVE_IW;

7.30,proposition,p:orlicz-hilo,Quantitative Orlicz high-low estimate,Orlicz and ergodic
estimates,conditional,"The complete real-Q high-low proposition is proved as an implication from the
recorded independent standard inputs. For every real Q>=2^k, one unchanged floor-Q arithmetic
construction supplies both prime and ordinary-square decompositions at the literal real-Q cutoff. It
retains period<=3^Q, rational coverage through Q, the literal denominator bound and goodness. Both
actual countable low bounds hold on all integer lp inputs at p_r, with the exact logarithmic real-Q
cost. Both actual high maxima share the same arithmetic set, period and selected Page datum and have a
proved summed Q^(-1/4) L2 bound above the stated exponential starting scale. All operator identities and
applicability are checked. The fixed absolute parameter constant is enlarged once from C to C^2; no
width is rounded and no own-paper endpoint is an external premise.","No own-paper deduction remains for
this proposition. The recorded independent general construction, multiplier/sampling,
continuous/signed-maximal, smooth multifrequency, Page/prime-distribution and scalar quadratic-Weyl
inputs remain explicit and unproved. Their hypotheses are not Lean axioms or assertions of
truth.",QUANTITATIVE_IW; GENERAL_VARIATION_SAMPLING; PROGRESSION_ESTIMATE; REN_GHOSH;

7.46,corollary,c:orlicz-ergodic,Ergodic transfer and quantitative endpoint conclusions,Orlicz and
ergodic estimates,conditional,"Complete printed Corollary7.46 as an implication of the explicit
independent inputs, for all three actual families and every invertible measure-preserving probability
system. One common C >= 1 serves the strong exponential rate and source Orlicz gauge; one common modular
multiplier is fixed before all systems, families, functions and levels. Every 1 < p <= 2 has the actual
strong maximal norm with almost-everywhere finiteness and actual Lp membership. The proper extended
maximum satisfies the source modular inequality. Every measurable Orlicz member at some positive scale
has actual averages converging almost everywhere and in L1 to the same genuine L1 limit, with
integrability of every average and both L1 seminorm/integral-norm convergence checked. Own truncation,
rescaling, Cauchy/density, L1 operator and limit-identification deductions are proved. At checkpoint1264
the current public export consumes the proved finite signed maximal theorem at constant6; a supplied
RawFiniteSignedMaximalInput and its constant R are no longer hypotheses.","No remaining printed clause
within the agreed conditional-formalization scope. The independent general Calderon strong/modular and
bounded-class polynomial convergence inputs, including their unproved published-theorem/normalization
bridges, remain explicit, as do the earlier Theorem7.2 independent inputs. Stronger standalone Section7
auxiliary ranges remain separately partial.",QUANTITATIVE_IW; GENERAL_VARIATION_SAMPLING;

9.17,proposition,p:sieveneedlower8,Lower sieve application,Goldbach and sieve,conditional,"Full source
lower-sieve proposition, including the actual representation sequence, original X_n and Euler product,
coefficients before n, a common error tending to zero, and the N^4(log N)^(-A) mean-square remainder
bound. The pointwise theorem holds throughout the source retained range (indeed all n=12 mod24). General
 classical sieve/Mertens/function-continuity and ordinary SW/BV/Ren-Ghosh inputs remain explicit and
unproved. At1229: Common cutoff compatibility for the circle-method and full lower-sieve estimates is
proved for every requested lower bound on C; main-term size remains to be joined. At1230: The full
source main-term size and the entire lower-bound side are complete conditionally, including an exponent
independent of C, uniform smoothing, one common large cutoff and finite error-to-exception deductions.
At1230 the source main-term size and the full lower sieve are proved jointly for the same C>=A0+6;
finite positive-count and exceptional-cardinality deductions are checked. At1258: All Section11 numbered
 claims are complete in the agreed conditional scope for the explicitly supplied corrected presieving
statement. The original weaker statement is not proved and must be replaced in the user manuscript. The
complete joint lower/upper estimates use one cutoff and n-independent coefficients, exact constants,
C_A0=A0/2+6 and arbitrary combined logarithmic mean-square saving. The final Goldbach theorem remains
the next deduction.",,ROSSER_IWANIEC_SINGLE_STAGE; CLASSICAL_INTERVAL_MERTENS;

9.20,proposition,p:sieveneedupper8,Upper sieve application and summed weights,Goldbach and
sieve,conditional,"The full source upper sieve is complete in uniform epsilon form, with the exact
c_(9/8) F_1(2) W(9/8) coefficient, original actual main term and closed multiplier set. All coefficients
 precede n; source divisor counts, refined preliminary/outer dimensions, uniform varying levels, the
shifted double remainder sum, its circle-method embedding and the fixed-sieve O(N^(1/4)) correction are
proved. The total error has arbitrarily strong logarithmic mean-square saving. Only independent general
SW, BV, Ren/Ghosh, classical one-stage sieve, effective multiplicative mean and Mertens inputs and
general sieve normalizations remain unproved; no own-paper endpoint is assumed. At1257: Full upper-sieve
 proposition p:sieveneedupper8 complete in uniform epsilon form from explicit independent classical
inputs, with the exact coefficient and arbitrary logarithmic mean-square saving. The lower analytic
estimate and both remainder transports are available at a shared prescribed cutoff. The final joint
Section11 assembly and manuscript synchronization are next. At1258: All Section11 numbered claims are
complete in the agreed conditional scope for the explicitly supplied corrected presieving statement. The
 original weaker statement is not proved and must be replaced in the user manuscript. The complete joint
 lower/upper estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and
arbitrary combined logarithmic mean-square saving. The final Goldbach theorem remains the next
deduction.",,BOMBIERI_VINOGRADOV; PROGRESSION_ESTIMATE; REN_GHOSH; ROSSER_IWANIEC_SINGLE_STAGE;

9.22,lemma,l:maintermsize8,Uniform lower bound for the sieve main term,Goldbach and
sieve,conditional,"Full source lemma proved for every A0>0 and every fixed C>=A0+6, uniformly over the
exact retained n range. The actual X_n Theta_n(z) is at least a positive constant times N(log

N)^(-(A0/2+6)); the exponent is independent of C. Actual archimedean, smoothing and local-product arguments are proved; only the already recorded independent interval Mertens products remain external. The same large C is joined to the complete lower sieve. At1258: All Section11 numbered claims are complete in the agreed conditional scope for the explicitly supplied corrected presieving statement. The original weaker statement is not proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic mean-square saving. The final Goldbach theorem remains the next deduction.",,CLASSICAL_INTERVAL_MERTENS,goldbach_archimedean_lower; goldbach_lower_arch_real; goldbach_lower_arithmetic_polylog; goldbach_lower_theta_inverse; goldbach_lower_main_term_size; goldbach_lower_smoothed_size; goldbach_lower_bounds_complete; goldbach_lower_bad_card; goldbach_section11_complete,blueprint/Checkpoint_1228_GoldbachArchimedeanLower.md; blueprint/Checkpoint_1230_GoldbachLowerMainTermSize.md; blueprint/Checkpoint_1258_GoldbachSection11Complete.md,6951,51bd2bb6d6448ded5e4c3ccd31a0fb3fb215c10682f374d1fb2c4802c4275158

9.24,lemma,l:numericalcomparison,Strict positivity of the sieve comparison,Goldbach and sieve,conditional,"The actual W integral has the unconditional exact bound 8 sqrt(2) W(9/8)<=9/32, proved by positive interval integration and exact rpow primitives. The strict comparison is proved for the classical normalized sieve values f_(1/2)(9/8)=sqrt(8 exp(gamma)/(9 pi)) log2 and F_1(2)=exp(gamma). Identifying the generic independent sieve functions with those classical normalized values remains explicit, within GENERAL_SIEVE; the paper comparison is not assumed. No floating point evaluation or unchecked evaluator is used. At1253: Proved the exact actual W integral bound, the normalized half/linear sieve comparison and strict positivity. Classical sieve-function normalizations remain explicit general input identities. The upper-sieve application and final Goldbach theorem remain open; no paper endpoint is assumed. At1258: All Section11 numbered claims are complete in the agreed conditional scope for the explicitly supplied corrected presieving statement. The original weaker statement is not proved and must be replaced in the user manuscript. The complete joint lower/upper estimates use one cutoff and n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic mean-square saving. The final Goldbach theorem remains the next deduction.",,GENERAL_SIEVE,goldbach_weighted_inner_linear_upper; goldbach_weighted_W_rational_upper; goldbach_sieve_numerical_comparison; goldbach_normalized_sieve_comparison; goldbach_section11_complete,blueprint/Checkpoint_1253_GoldbachSieveNumericalComparison.md; blueprint/Checkpoint_1258_GoldbachSection11Complete.md,6963,f00144cc10f16f6c3e1fb11f0dea31de17044c8759302b963fe4ca9c308eaeb7

10.2,lemma,l:hybridminorarc,Hybrid minor-arc mean-square estimate,Goldbach and sieve,conditional,"Complete source hybrid minor estimate at1136: the actual circle integral and finite $n<N^2$ mean square, exact complementary source arcs, every sufficiently large radius exponent C, and a single natural threshold uniform in all coefficients, residues, real U and W and printed strict L_0/V_{ell} ranges. The theorem allows $B\ge 0$ and $0\le U\le N$, with arbitrary W and residues, so it is stronger than the stated ranges. Explicit bound $K\,N^4(\log N)^{-A}$, $K=Z^2(256/\log 2)$, $Z=(2P+3)/\log 2$, $C_0=3A+4d+26$. Finite Abel, prime-power removal, halving reconstruction, scale transfer, eventual cutoffs, source progression energy and Bessel are proved. Only the already recorded independent raw Ren/Ghosh input is assumed.",The independent raw UniformRenGhoshInputs remains explicit and unproved. The source hybrid minor conclusion and all conversion steps are discharged; no internal own-paper hypothesis remains.,REN_GHOSH,goldbach_weighted_full_fourier_inversion; goldbach_actual_minor_bessel; goldbach_major_minor_partition; goldbach_circle_three_stage_bound; goldbach_frequency_energy_identity; goldbach_progression_energy_le_collisions; goldbach_actual_minor_collision_bound; goldbach_prime_collision_off_diagonal; goldbach_reciprocal_lcm_harmonic_cube; goldbach_reciprocal_lcm_log_cube; goldbach_reciprocal_lcm_strict_real_cutoff; goldbach_congruence_interval_card; goldbach_simultaneous_congruence_count_real; goldbach_congruence_square_identity; goldbach_congruence_square_harmonic_bound; goldbach_congruence_square_strict_real_cutoff; goldbach_frequency_energy_multiplicity; goldbach_prime_product_fibre_card; goldbach_prime_product_energy; goldbach_index_row_sum; goldbach_progression_polynomial_by_rows; goldbach_progression_energy_by_row_squares; goldbach_total_row_square_bound; goldbach_progression_energy_harmonic; goldbach_progression_energy_log_five; goldbach_source_energy_numerical_ranges; goldbach_source_progression_energy; goldbach_source_progression_energy_printed_range; goldbach_minor_logarithmic_exponents; goldbach_hybrid_minor_from_pointwise; goldbach_finite_abel_bound; goldbachLogRemovalWeight_antitone; goldbachLogRemovalWeight_of_two_le; goldbach_log_removed_mangoldt_bound; goldbach_prime_power_log_removal_error; goldbach_prime_from_mangoldt_partials; goldbach_halving_partial_bound; goldbachMangoldtPrefix_annular_norm; goldbach_mangoldt_partials_from_annular; goldbachMinorArcs_measurable; goldbach_minor_arcs_source_centres; goldbach_minor_arcs_rescale; goldbach_common_annular_minor; goldbach_prime_minor_from_numeric_parameters; goldbach_log_minor_radius_identity; goldbach_log_minor_annular_budget; goldbach_prime_minor_log_parameters; goldbach_minor_real_eventual_budgets; goldbach_minor_eventual_numeric_parameters; goldbach_prime_minor_uniform; goldbach_prime_minor_source_cutoff_algebra; goldbach_prime_minor_source_high_range; goldbachHybridMinorConstant_pos; goldbach_hybrid_minor_complete,blueprint/Checkpoint_1116_GoldbachMinorArcBessel.md; blueprint/Checkpoint_1117_GoldbachProgressionEnergy.md; blueprint/Checkpoint_1118_GoldbachReciprocalLCM.md; blueprint/Checkpoint_1119_GoldbachCongruenceCounting.md; blueprint/Checkpoint_1120_GoldbachCongruenceMultiplicity.md; blueprint/Checkpoint_1121_GoldbachPrimeFrequencyEnergy.md; blueprint/Checkpoint_1122_GoldbachProgressionRows.md; blueprint/Checkpoint_1123_GoldbachLogarithmicEnergy.md; blueprint/Checkpoint_1124_GoldbachSourceEnergy.md; blueprint/Checkpoint_1125_GoldbachHybridMinorReduction.md; blueprint/Checkpoint_1128_GoldbachFiniteAbel.md; blueprint/Checkpoint_1129_GoldbachPrimeUnweighting.md; blueprint/Checkpoint_1130_GoldbachHalvingPartials.md; blueprint/Checkpoint_1131_GoldbachMinorArcGeometry.md; blueprint/Checkpoint_1132_GoldbachUniformAnnularMinor.md; blueprint/Checkpoint_1133_GoldbachMinorLogParameters.md; blueprint/Checkpoint_1134_GoldbachMinorEventualCutoffs.md; blueprint/Checkpoint_1135_GoldbachPrimeMinorUniform.md; blueprint/Checkpoint_1136_GoldbachHybridMinorComplete.md,7094,dbf2e41e83c506da3fab97ff32314503684b1f887470d2ffc7cfe10d73d8e6fb

10.12,lemma,l:positiveH9,Positivity and truncation of the singular integral,Goldbach and sieve,proved," At1176: The actual normalized autocorrelation cutoff has a proved positive denominator, exact convolution integral, eta(0)=1 and real nonnegative inverse Fourier transform. At1177: The scaled actual eta_N and its square have proved real nonnegative inverse Fourier transforms and exact compact support inherited from the seed. At1178: The actual eta is real, even, bounded by1, has zero derivative at0 and satisfies the full global quadratic source cutoff bound. At1179: Two-sided absolute integrability and an

explicit L1 estimate are proved from the exact finite-scale bound and inverse-three-halves tail. At1180: The exact cutoff-weighted Fourier integral is a proved positive average of the inverse kernel, with Fubini integrability discharged. At1181: The actual source singular integral is proved real nonnegative, uniformly in all positive ell and every real n, including the empty-domain branch. At1182: The actual Euclidean product and smoothed integrand are globally integrable, and the exact source singular integral satisfies a proved uniform O(N) bound for all positive ell. At1183: The full quantitative real-line smoothing error bound is proved with absolute constant6 and every integrability condition discharged. At1184: The actual smoothed and unsmoothed source integrals satisfy the full uniform O(N/sqrt(R)) comparison, with all integrability and empty-domain branches proved. At1185: The actual quadratic affine density is globally integrable and has the proved exact product Fourier transform, including the scale factor. At1186: The genuine logarithmic quadratic density is continuous and integrable, with its exact source product Fourier transform proved and endpoint exceptional sets checked. At1187: The full source l:positiveH9 is proved: the exact autocorrelation cutoff, real nonnegative smoothed singular integral, its exact printed one-variable H_ell domain, and the uniform O(N/sqrt(R)) comparison, including all positive ell and empty-domain cases. There is no independent analytic input for this lemma. At1213: Completed every Section10 source statement and the full source circle-method implication, including the original smooth compact seed and exact normalized integral. Only the three agreed independent raw deep inputs remain for this circle-method implication.","None. Positivity and the comparison with the exact printed one-variable domain are proved for the actual source cutoff and integrals, without extra external analytic input.",,goldbach_autocorrelation_integral; goldbach_seed_mass_pos; goldbach_eta_zero; goldbach_autocorrelation_fourier; goldbach_eta_inverse_fourier_nonnegative; goldbach_inverse_fourier_scale; goldbach_scaled_eta_inverse_nonnegative; goldbach_cutoff_square_inverse_nonnegative; goldbach_eta_support; goldbach_scaled_eta_support; goldbach_eta_real; goldbach_eta_even; goldbach_autocorrelation_norm; goldbach_eta_norm_le_one; goldbach_eta_deriv_zero; goldbach_eta_quadratic; goldbach_eta_square_cutoff_bound; goldbach_halfline_integrable_decay; goldbach_two_sided_integrable_decay; goldbach_cutoff_fourier_fubini; goldbach_positive_cutoff_fourier_average; goldbach_euclidean_product_density; goldbach_singular_integral_positive; goldbach_singular_integral_empty; goldbach_singular_integral_nonnegative; goldbach_euclidean_product_integrable; goldbach_singular_integrand_integrable; goldbach_singular_integral_norm; goldbach_smoothing_power_identity; goldbach_smoothing_decay_integrable; goldbach_singular_smoothing_uniform; goldbach_affine_integral; goldbach_quadratic_density_joint; goldbach_quadratic_average_integrable; goldbach_quadratic_average_fourier; goldbach_log_window_integrable; goldbach_log_window_continuousAt; goldbach_source_density_integrable; goldbach_source_density_fourier; goldbach_source_density_continuous; goldbach_archimedean_integral_domain; goldbach_source_density_archimedean; goldbach_source_unsmoothed_inverse; goldbach_unsmoothed_archimedean_complete; goldbach_smooth_compact_seed_nonzero; goldbach_eta_of_smooth_compact_seed; goldbach_positive_singular_integral_complete; goldbach_source_singular_integral_eq; goldbach_circle_method_source_complete; goldbach_source_singular_integral_positive_comparison,blueprint/Checkpoint_1176_GoldbachAutocorrelation.md; blueprint/Checkpoint_1177_GoldbachScaledCutoff.md; blueprint/Checkpoint_1178_GoldbachCutoffBounds.md; blueprint/Checkpoint_1179_GoldbachIntegrableDecay.md; blueprint/Checkpoint_1180_GoldbachPositiveFourierAverage.md; blueprint/Checkpoint_1181_GoldbachSingularIntegralPositive.md; blueprint/Checkpoint_1182_GoldbachSingularIntegralNorm.md; blueprint/Checkpoint_1183_GoldbachSmoothingDecay.md; blueprint/Checkpoint_1184_GoldbachSingularSmoothing.md; blueprint/Checkpoint_1185_GoldbachQuadraticDensity.md; blueprint/Checkpoint_1186_GoldbachSourceDensity.md; blueprint/Checkpoint_1187_GoldbachPositiveSingularComplete.md; blueprint/Checkpoint_1213_GoldbachCircleSourceSeed.md,7266,1419a1d8a16e5afefcc947e401c77b09483f681945a947c342ce052c3e3002e2
10.15,lemma,l:majorapproximation9,Replacement by the major-arc models,Goldbach and sieve,conditional,"At1126: The exact lcm-fibre divisor bound and weighted progression-error reindexing for the major arcs are proved. At1137: Exact strict-cutoff reduction and a uniform one-term endpoint error are proved for the actual progression sums. At1138: The exact prime counting and logarithmic-integral progression models, derivatives and lower-endpoint identities are proved. At1139: The actual prime-count discrepancy is transported through every smooth unit phase with an explicit quantitative error, including the lower prime endpoint. At1140: Exact positive-phase linear and quadratic partial-summation errors are proved from ordinary prime-counting discrepancies, with signs and totient normalizations checked. At1141: The actual prime-square major-arc model and explicit nonunit/count-discrepancy error are proved with the exact source sign and normalization. At1142: The fixed-q lcm fibre bound and complete reduction to ordinary unweighted modulus-distribution errors are proved. At1143: The compatible lcm residue sets, q-cardinality bound and generalized CRT existence/converse are proved for arbitrary positive moduli. At1144: The exact Upsilon coefficient for the actual compatible lcm residue classes is proved, including both signs and totient factors. At1145: The exact independent ordinary prime-count SW/BV boundaries are implemented; real-error equivalence, square-model numeric bound and logarithmic absorption are proved. At1146: The full uniform source SW prime-square major approximation is a complete deduction from the independent ordinary prime-count SW input. At1147: Exact prime progression residue fibres and positive rational-phase grouping are proved for the actual finite sums. At1148: The actual source linear model and all nonunit/strict-endpoint errors are proved from ordinary lcm-modulus prime-count discrepancies. At1149: The actual strict source J integral, clamped prime cutoff, and uniform numeric linear model error are matched exactly. At1150: Actual BV row approximation is proved under the independent ordinary unweighted BV input, with individual progression cutoffs and all finite exceptional terms retained. At1151: The printed source ranges imply the ordinary BV level and comparable logarithmic saving, with a threshold uniform in every active ell. At1152: The actual source row-scale sum and coefficient-family cardinality square bound are proved, including all empty-cutoff cases. At1153: Every retained prime endpoint/nonunit term is absorbed uniformly from the exact printed source ranges, using a proved power saving. At1154: The full uniform source BV progression-error norm sum is complete under the independent ordinary unweighted BV input, with all individual cutoffs and finite errors included. At1155: Exact source major-set geometry, normalized measure, wrap-around lifts, pairwise disjointness and eventual separation are proved. At1156: Measurable local coordinates and genuine Euclidean model regularity and norm bounds are proved for the circle Bessel assembly. At1157: The exact source major models are constructed on the circle, with proved localization and all-Lp regularity and the required square size bound. At1158: Both full SW/BV major estimates now hold for the constructed exact source circle models, uniformly in every printed parameter. At1159: The restricted measurable Bessel inequalities and two-model major-arc mean-square assembly are proved. At1160: The actual weighted source coefficient identity, model Lp bounds and complete logarithmic mean-square budget are proved. At1161: The full source major-arc mean-square approximation l:majorapproximation9 is complete under ordinary SW and BV, uniformly in all printed data, with strict endpoints and finite errors discharged.",No unmatched clause remains in this lemma. The independent ordinary SW and BV proofs remain external; apply

10.20,lemma,l:arithmeticcoefficients9,Goldbach arithmetic coefficients and Euler series,Goldbach and
sieve,proved,"Completed Section 3 identities are reusable; this full statement is not counted as partial
 merely because it cites them. At1162: The actual inclusive R-smooth arithmetic series is absolutely
summable, equals the source finite Euler product and admits an exact finite cutoff/tail split. At1163:
The genuine Euclidean source integrals have proved quadratic and linear frequency decay, with explicit
constants and all cutoffs retained. At1164: Unconditional reciprocal-totient harmonic estimates,
including arbitrary divisor progressions, and the exact gcd divisor expansion are proved. At1165: The
full source arithmetic-family harmonic estimate is proved unconditionally with explicit divisor
exponent2 and constant9 exp(2). At1166: Exact arbitrary-multiplier coefficient identities and the
uniform odd-prime bound8 gcd(p,k*ell)/p are proved. At1168: The genuine coefficient has a uniform
prime-power gcd bound, with every two-adic exponent handled explicitly. At1169: General-modulus source
coefficient decay tau(q)^9 gcd(q,k*ell)/q and principal Gauss decay tau(q)^3/sqrt(q) are proved
unconditionally. At1170: The actual weighted source arithmetic-family and finite denominator-tail bounds
 are proved; the full source arithmetic and completion lemmas remain open with explicit remaining
clauses. At1171: Normalized finite unit averages are proved invariant under reduction to every divisor
modulus. At1172: Primitive progression exponential cancellation and the coprime norm bound are proved
from actual finite unit sums. At1173: The actual Upsilon coefficient is an exact lcm-unit expectation
and satisfies exact simultaneous frequency/denominator reduction. At1174: The actual Upsilon coefficient
 has the proved sharp gcd/divisor decay tau(q) gcd(q,k*ell)/q. At1175: The full source
arithmetic-coefficient lemma is proved: absolute convergence, the all-prime infinite local Euler series
and its exact source G_R value, all three individual bounds with the common divisor exponent9, and the
complete real-cutoff harmonic family estimate. There are no external inputs for this lemma.",None. All
clauses are proved under the source hypotheses; no extra external mathematical

11.2,lemma,l:fixedsievesets10,Comparison with fixed sieve prime sets,Goldbach and sieve,proved,"Complete
 lower and upper fixed-sieve comparison, with actual sieve prime sets and actual closed multiplier set.
The lower inequality is proved by inclusion, including the prime3 boundary. The upper comparison uses an
 exact finite exceptional-pair inclusion and the bound sum over p|n of tau(n-p^2-1) <= K_epsilon
N^epsilon. One positive constant is chosen before N,n,z. Holds for every N>=1,0<n<=N^2 and every real z,
 hence the full retained source range. No deep input is used. At1215: The full source fixed-sieve
comparison is proved without deep inputs. The local density, presieving and final sieve estimates remain
 open.",None within the source fixed-sieve comparison lemma.,,goldbach_fixed_lower_count;

11.6,lemma,l:lowerlocaldensity,Lower-sieve local density formula,Goldbach and sieve,proved," At1216:
Proved the exact lower sieve sequence/progression count and its actual circle-method remainder
decomposition. The full fixed-sieve comparison remains proved; local densities and later sieve
conclusions remain open. At1219: Actual unit-square root counts, both candidate prime-density bounds
including p=5, and the explicit multiplicative sieve function are proved without deep inputs. Full
local-density normalization is the next internal obligation. At1220: Proved the conductor-sensitive
coefficient identity, all actual prime-factor cases, the exact factors at2 and3, residue invariance, and
 normalized prime adjunction without division by the global base factor. Full local-density source
closure is reserved for the final product and CRT assembly. At1221: complete actual normalized
Euler-product factorization, exact source CRT residues, inclusive prime cutoff, multiplicativity and all
 density bounds are proved without external inputs. The upper base factor may vanish; no division by it
is used. At1221: Both full source local-density lemmas are proved without new external inputs: exact
original Euler normalization, inclusive cutoff, lower quotient identification, source CRT
specializations, upper multiplicativity and p=5, with common zero upper base factors retained.
Presieving and the later sieve estimates remain open.",None within the source statement and retained

11.13,lemma,l:presieving,Two-range presieving deduction,Goldbach and sieve,conditional,"The corrected
two-range presieving statement is a complete implication from the explicit independent general one-stage
 sieve inputs. The exact source matched is the separately supplied Section11_Reconciled.tex: X>=0,
g(1)=1, fixed R=(log N)^C, R+1<=z<=D1<=N^A, refined1+K/logw dimension bounds, and the preliminary
endpointR+1. Coefficients precede the density/sequence and n, have absolute value<=1 and exact level
support; the common relative error tends to zero. The literal original weaker manuscript statement is
not claimed proved; replacement is required in the user manuscript. No original source file was changed.
 At1258: All Section11 numbered claims are complete in the agreed conditional scope for the explicitly
supplied corrected presieving statement. The original weaker statement is not proved and must be
replaced in the user manuscript. The complete joint lower/upper estimates use one cutoff and
n-independent coefficients, exact constants, C_A0=A0/2+6 and arbitrary combined logarithmic mean-square

saving. The final Goldbach theorem remains the next deduction. At1265 the uploaded human-readable
statement is reviewed directly: D0<D follows from its level chain, and the inline interval prime
conditions are proved equivalent in Lean. The corrected mathematical hypotheses are verified as present
in the actual upload; no presieving replacement remains outstanding.",,GENERAL_SIEVE;

11.19,lemma,l:wumatomakisum,Weighted upper main-term comparison,Goldbach and sieve,conditional,"Complete
 source weighted upper main-term comparison, in uniform epsilon form, with the actual multiplier set,
local factors, finite Euler products and singular integrals. For every A>0, every fixed C>=A+24 and
eta>0, one threshold in N works for all n=12 mod24 with N^2(log N)^(-A)<=n<N^2. The coefficient is
exactly c_(9/8) W(9/8)+eta. Strong multiplicativity, the uniform mean instantiation, both finite Abel
arguments, W identity, all small-denominator and endpoint terms, moving logarithms, integration,
smoothing and relative errors are proved. Only the independent generic effective mean-value corollary
and classical fixed-progression Mertens bounds remain explicit unproved hypotheses. The source lemma
statement is unchanged; two proof replacements are supplied but not applied. At1252: The full source
weighted upper main-term comparison l:wumatomakisum is complete as a checked implication from
independent generic effective mean-value and classical Mertens inputs, with the exact printed constant,
actual source definitions, uniform retained-range quantifiers, and every summation, integration and
relative-error obligation discharged.",,EFFECTIVE_HALF_DIMENSIONAL_MEAN; CLASSICAL_PRIME_LOG_MERTENS;

      ],
      "scope": "Both parts are complete conditional implications. Part(i): the actual enumerated prime
squares are persistently universally L1-bad on every truly nonatomic ergodic measure-preserving
probability system, with every infinite cutoff set and an actual measurable positive-measure divergence
set. CRT, Dirichlet representation, correlation counts, large-prime block construction, all
moment/thickening/difference limits, uniform square-root fibers and the fixed-progression PNT
pushforward are proved. The original badness theorem, Sawyer, Conze, general Weil and fixed-progression
PNT remain separate unproved general inputs. Granville\u2013Kurlberg is not used by part(i). A checked
moment proof replaces the source strict finite-fraction argument, which has an exact kernel
counterexample. Part(ii) is a complete conditional implication: an absolute positive constant before
every invertible measure-preserving probability system, every 1 < p <= 2 and every Lp input; the proper
actual maximum over the first m prime squares for all m >= 1 is finite almost everywhere, belongs to Lp
and has the exact displayed exponential norm bound. The prime-counting/enumeration normalization, finite
 sums, first-prime case and equality of both full maxima are proved with no PNT or enumeration input.
The proof uses the already proved Corollary7.6 and the precise independent general strong Calderon
input, plus the earlier Theorem7.2 independent inputs. It does not use the bounded-class convergence
input. At checkpoint1264 the current public export consumes the proved finite signed maximal theorem at
constant6; a supplied RawFiniteSignedMaximalInput and its constant R are no longer hypotheses.",
      "remaining": "No remaining source clause within the agreed conditional scope. General inputs and
their exact convention bridges remain unproved. The user confirmed the three Section8 edits; the

      ],
      "scope": "The full quantitative exceptional-set theorem is complete: for every A>0, the actual
exceptional set of positive n<X congruent12 mod24 without a prime plus a square-of-prime representation
whose first prime is a primitive sum of two squares plus1 has size O_A(X(log X)^(-A)), eventually at
every real X. The representation and exceptional-set membership are exact. The common-cutoff Section11
estimates, positive numerical gap, arbitrary logarithmic mean-square saving, all arithmetic losses,
small n and the passage from N^2 to real X are discharged. Explicit independent general SW, BV,
Ren/Ghosh, one-stage sieve, effective multiplicative mean, Mertens, normalized sieve values/continuity
and primitive two-square criterion remain unproved theorem parameters. No own-paper endpoint is a
hypothesis. At1259: Section11 and the final quantitative Goldbach theorem are complete in the agreed
conditional scope, using the supplied corrected presieving statement. Every paper endpoint is
discharged; only explicit independent general classical inputs and their normalizations remain unproved.
 Original manuscripts are unchanged and the supplied Section11 replacements still require user
application. No additional completion credit is claimed for stronger unnumbered assertions in alternate
proof routes. At1261: Proved the full PrimitiveTwoSquaresCriterion from pinned Mathlib and elementary
algebra, and proved W(alpha) convergence/nonnegativity for every alpha>1. Constructed a concrete nonzero
 compactly supported smooth seed. The next stage exports the Section9 arithmetic and headline statements
 without the former criterion or seed hypotheses, then reconciles the stale Section9 map. User
manuscript edits remain in progress. At1262 the final endpoint is exported from GoldbachSection11Inputs
alone: the primitive two-square criterion is proved internally and a fixed nonzero smooth compact seed
is constructed. The real-X bound and zero exceptional density need no separate arithmetic or seed
assumption. At1262: Every Section9 numbered source claim and its final quantitative theorem is complete
in the agreed scope. All elementary arithmetic reductions are now proved without an extra primitive
two-square assumption. W(alpha) convergence is proved for every alpha>1 and the smooth seed is
constructed. Only the explicit independent analytic inputs remain for the circle-method/sieve/headline
estimates. The user is applying previous manuscript edits; no application is assumed and original
sources are unchanged.",
